

Mars Sample Return ascent trajectory optimisation using Taylor Series integration

Master Thesis

S.D. Petrovic

Faculty Aerospace, Section Spaceflight

PREFACE

Back in December 2013 Warren Gebbett gave a presentation on his work at the Jet Propulsion Laboratory (JPL) in Pasadena, California, USA and the opportunity for a new student to go and perform research at JPL. At this point I sent in my application together with eight other students. Then at the end of December I heard that I was invited for an interview in the first week of January 2014. In this interview it was concluded that I met all the requirements and that I was the perfect candidate to follow Warren up as the next student at JPL with financial backing of Dutch Space (now Airbus Defence and Space, the Netherlands). Financial backing was also going to be provided by the Stichting Prof.dr.ir. H.J. van der Maas Fonds (Aerospace Engineering Faculty, TU Delft) and the Stichting Universiteitsfonds Delft (TU Delft). Communication with JPL was thus started and in March 2015 it was clear that I would be working for the Mars Program Formulation Office under the supervision of Roby Wilson (Inner Solar System group, NASA JPL). He told me to focus on subjects that dealt with Mars missions. At that point I was doing my internship at DLR Bremen on Lunar rocket ascent and descent, which lasted till June 2015. When I came back to Delft me and my supervisors Erwin Mooij (rockets, trajectories, entry and descent, TU Delft) and Ron Noomen (mission design and orbit analysis, TU Delft) agreed that it would be best to perform a study on these Mars subjects to prepare for my visit to JPL and to formulate proposal thesis topics. The first week at JPL I presented these initial thesis topics to both people from the Inner Solar System group and the Mars program formulation office. The next few weeks were spent choosing and refining one of these topics. This document is the result of the two-month literature study on that topic to prepare for the thesis project.

INTRODUCTION

Mars Sample Return (MSR) has been a mission concept that has been proposed many times in the past two decades. Even today, research into this mission is still being done. And although it is not yet an official project proposal, NASAs Jet Propulsion Laboratory (JPL) is currently working on pre-cursor missions to eventually launch an MSR mission. To prepare for this, research is being conducted on different aspects of MSR, such as the Mars Ascent Vehicle (MAV) responsible for transporting the dirt and soil samples into a Martian orbit and the orbiter which will then transport the samples back to Earth. The current orbiter proposed by JPL is a low-thrust orbiter called Mars 2022. Such an MSR mission requires precise and optimum (optimised for lowest Gross Lift-Off Mass (GLOM)) trajectories to be able to bring back as many samples as possible. But how does one determine the optimum MAV trajectory? Especially when it is combined with the optimum trajectory of the low-thrust orbiter.

The proposed research would focus on the combined optimisation of an MAV trajectory and the trajectory of the low-thrust Mars 2022 orbiter. Also, one hypothesis is that great mass saving can be made if the orbiter and MAV would rendezvous within one single orbital revolution after MAV lift-off. Therefore, the question that should be answered is: what is the optimal trajectory solution for the combined trajectory problem of a high-thrust MAV and a low-thrust Mars orbiter performing a single-revolution rendezvous in Mars orbit? More information on the proposed topic is provided in ??.

A mission such as MSR and the corresponding trajectories can be described in many different reference frames, or Frame of Reference (RF), and the motion of the MAV and the orbiter can be modelled in different ways. Therefore it is important to use the proper equations and environmental models. Also, the trajectory has to be determined or rather a prediction will have to be made. This can be done using integration methods. And finally, the optimum will have to be found using an optimisation method. All these different aspects are addressed in this literature study.

First however, it is important to determine the knowledge that already exists and the research that has already been performed. Therefore, ?? will describe previous sample return missions, low-thrust Spacecraft (s/c) missions, single-revolution rendezvous missions and the research performed in those fields. It will also describe the current MAV designs. Then before mathematically representing the problem it is important to understand in what kind of RF it has to be described. This will be done in ??, followed by the MAV ascent and low-thrust Mars 2022 orbiter model descriptions in ???? respectively. Here, both chapters explain the assumptions and corresponding equations for each phase. One important aspect of the MAV ascent, which sets it apart from other sample return missions, is that Mars has an atmosphere which cannot be neglected. Accordingly ?? describes the different atmospheric models and the trade-off that was performed to decide which model to use in this thesis problem. Then the integration and optimisation are discussed in ?? and chapter 4 respectively. In the integrators chapter, different integration methods are described and a selection is made of the integration methods that will be used. The same is done for the different optimisers. All of this information will be used to define the final thesis topic, which is presented in ??. For some of the aspects that will be treated in the final thesis problem, certain software is already available. A summary of this software is provided in ??. Finally, a proposed schedule is presented in ??, which shows the work which will have to be performed during the thesis work and the time that will have to be spend on each aspect of it. This literature study will serve as a guideline during the thesis project and provide background information for the final thesis report.

2

PROBLEM BACKGROUND

3

MODELS

The MAV and the corresponding ascent can be modelled in many different ways. Depending on the desired accuracy of the final solution compared to the real-life expected trajectory, different perturbations and freedom in motion can be defined and included, ranging from a low fidelity to a high fidelity program. The main goal of this thesis is to determine if TSI is an integrator that can be used for ascent cases and determine its performance compared to previously established methods. Therefore, it should be close to a real-life ascent, but not include too many aspects as to make the problem too complex to test. Therefore, it was decided to design a low fidelity program to propagate the trajectory using accelerations in the x-, y- and z-direction (3DOF). The MAV system can then be modelled as a point-mass system with different accelerations acting on it. The change in position can be described by the kinematic equations and the change in velocity by the corresponding dynamic equations. The change in mass is then described by the mass-flow. All these equations are provided in Section 3.1. For this model, three perturbing accelerations will be taken into account: the gravity, the thrust and the drag. The effect of third bodies can be neglected because of the short mission time. All the accelerations are described in Sections 3.2 to 3.4 respectively.

3.4.1. ATMOSPHERIC GRAPH FUNCTION FIT

Using Mars-GRAM 2005, a table containing altitude, latitude and longitude dependent temperature and density data was produced. The altitude range was -0.6 to 320 km Mars Orbiter Laser Altimeter (MOLA) with a step-size of 0.01 km, the latitude and longitude ranges were centred around the launch site (21.0 °N and 74.5 °E) with a 10 degree range in each direction and a step-size of 1 degree. The rest of the input parameters were constant and can be seen in Appendix A. The temperature and density data produced is shown in Figures 3.1 and 3.2 respectively for 9 latitude and longitude combinations including the launch site itself.

Unfortunately discontinuous data tables cannot be used when integrating using TSI, which is why both these data tables had to be fitted with continuous functions. The temperature data could not be smoothly fit with one continuous function. Therefore, depending on the altitude range, a different approximation function is required. The condition to be met for a proper fit came from the differences in the temperature-altitude and density-altitude curves, where the maximum difference with respect to the launch site curve was taken. The requirement for the standard deviation of the polynomial curve fit was then to be (at least) one order lower than this maximum difference and that the maximum difference between the fit and the launch site curve was lower than the maximum difference. The temperature-altitude curve was split into 5 sections as roughly visualised in Figure 3.3. The number of sections come from both the shape of the curves and the requirement for accuracy and maximum order of the polynomial, which is set at 8 because otherwise the polynomial would get too long. Also, the number of sections were to be kept at a minimum. More information on the fitting process and early results is provided in Appendix B.

Figure 3.1: Temperature data generated with Mars-GRAM 2005 showing 9 different latitude and longitude combinations

Each section was fit with a polynomial function of the n^{th} order where the function is represented by Equation (3.1). The last section shows a constant temperature, thus the temperature of the launch site curve was chosen to represent this final section, which is equal to 136.5 K.

$$y = p_n x^n + p_{n-1} x^{n-1} + \dots + p_1 x + p_0 \quad (3.1)$$

A lower order is preferred, because then the fitted function will be simpler to evaluate and contain fewer terms. However the order has to be high enough to meet the accuracy requirements. Table 3.1 shows the orders that were required and the deviations to the launch site temperature-altitude curve. The actual corresponding parameters are provided in Table 3.2. It should be noted that the first few temperature data values were so different from the rest of the curve that it was assumed that this is a lack of the Mars-GRAM program and were thus treated as outliers.

Table 3.1: Temperature curve fit data all with respect to the launch site curve (Latitude and longitude of the launch site)

Section	Altitude range [km MOLA]	Order	Maximum poly-nomial standard deviation [K]	Maximum poly-nomial difference [K]	Maximum data curves difference [K]
1	-0.6 to 5.04	1	0.0312	25.8	0.177
2	5.04 to 35.53	2	0.287	3.90	0.7056
3	35.53 to 75.07	6	0.624	8.00	1.69
4	75.07 to 170.05	8	0.523	6.60	2.45

The complete polynomial fit for the launch site curve for the temperature is shown in Figure 3.4.

Figure 3.2: Density data generated with Mars-GRAM 2005 showing 9 different latitude and longitude combinations

Table 3.2: Temperature curve fit parameters (rounded to 3 decimal points)

Section	p ₈	p ₇	p ₆	p ₅	p ₄	p ₃	p ₂	p ₁	p ₀

2							0.006	-2.130	222.052
3			-5.388 ·10 ⁻⁷	1.785 ·10 ⁻⁴	-0.0243	1.733	-68.294	1.407 ·10 ³	-1.167 ·10 ⁴
4	4.1942 ·10 ⁻¹²	-4.328 ·10 ⁻⁹	1.931 ·10 ⁻⁶	-4.862 ·10 ⁻⁴	0.076	-7.405	447.378	-1.523 ·10 ⁴	2.236 ·10 ⁵

The density fit was slightly more difficult because the curves are all very similar and thus result in a higher accuracy requirement for the fit. At first glance it looks like a natural logarithmic function, unfortunately an ordinary exponential did not fit the curve. This is why a more extensive exponential fit was required. The natural logarithm of the data has been plotted in Figure 3.5.

With the data represented in the logarithmic domain, again a polynomial function can be fit. The total fit would then satisfy Equation (3.2).

$$y = \exp(p_n x^n + p_{n-1} x^{n-1} + \dots + p_1 x + p_0) \quad (3.2)$$

The same polynomial requirements as for the temperature curve were enforced for the density curve as well. However, because the polynomial is used in an exponential, some extra requirements are needed to assure the accuracy of the fit. One requirement is that the maximum difference between the final exponential fit and the normal launch site density curve is smaller than the maximum difference between all the data curves. Also, in this case the standard deviation of the difference between the exponential fit and the normal launch site curve had to be within the range of standard deviations of the difference between the different

Figure 3.3: Different temperature curve sections

data curves. This meant that even though an 8^{th} order polynomial fit could be achieved for the natural logarithmic data with the required accuracy, when converted to the exponential fit, the last two requirements were not met. Before it was mentioned that an order higher than 8 was not desirable. However, in this case, a single exponential fit could be achieved using a 10^{th} order polynomial. This fit meant that the density curve did not have to be split up at all, which makes the integration slightly easier. Therefore, it was decided that a 10^{th} order polynomial was acceptable in this case. The results of the fit is presented in Tables 3.3 and 3.4 and the polynomial and exponential fit curves are shown in Figures 3.6 and 3.7 respectively.

Table 3.3: Density curve fit data (10^{th} order polynomial) with respect to the launch site curve (Latitude and longitude of the launch site)

Maximum polynomial standard deviation [kg/m³]	0.0501
Maximum polynomial difference [kg/m³]	0.160
Maximum natural logarithmic data curves difference [kg/m³]	0.460
Maximum exponential difference with launch site curve [kg/m³]	$2.826 \cdot 10^{-3}$
Maximum data curves difference [kg/m³]	$3.910 \cdot 10^{-3}$
Standard deviation exponential fit difference [kg/m³]	$1.167 \cdot 10^{-4}$
Maximum standard deviation data curves difference [kg/m³]	$2.106 \cdot 10^{-4}$

Figure 3.4: All section fits for the launch site temperature data curve

3.4.2. DRAG COEFFICIENT GRAPH FUNCTION FIT

Similar to the temperature and density curves, the relation between Mach number and drag coefficient, as depicted in Figure 3.8, had to be modelled as a continuous function as well. Again, it could not be fitted using one continuous function, but instead had to be modelled by different functions.

Fortunately, this curve is already an approximation and thus consists of linear elements only. It can be split up into 6 different sections where the first and last section are constant (C_D is 0.2 and 0.3 respectively). Using a similar polynomial fit as before, but now for 1 order only, a linear fit could be made for each of the remaining 4 sections. The corresponding parameters are shown in Table 3.5 and the curve fit is shown in Figure 3.9.

Table 3.5: Drag coefficient curve fit parameters (rounded to 3 decimal points)

Section	Mach range	p_1	p_0
2	0.5 to 1	0.400	$-2.483 \cdot 10^{-16}$

OPTIMISATION

5

STANDARD INTEGRATION METHODS

6

TAYLOR SERIES INTEGRATION

Taylor Series integration (TSI) is different from the previously mentioned integrators, because it only uses the information at the current point to predict the next point. However, it does this using higher order derivatives at that point. These higher order derivatives have to be obtained as a function of the current state and the first order state derivatives. As soon as the K^{th} order derivative has been found, a Taylor Series can be set up to determine the next state as a function of the chosen step-size. This is all explained and described in more detail in Section 6.1. In this thesis, TSI is the main focus of the analysis. The performance with respect to the RKF integrators is tested. In order to be able to do this for the given model, a number of equation sets can be identified which have to be written in such a format that it can be used by TSI. These are described, and where needed derived, in Section 6.2.

6.1. GENERAL THEORY

TSI has been used to solve ordinary differential equations since the early 1960s (Scott and Martini, 2008). However, the first modern implementation of TSI in a space trajectory problem was provided by Montenbruck (1992). Scott and Martini (2008) were able to implement this TSI method into the SNAP trajectory propagator which is the implementation that is used in this thesis. The method is described in Section 6.1.1 and the used step-size method is discussed in Section 6.1.2.

6.1.1. WORKINGS OF TSI

The formulation used in this thesis is based on the one used by Scott and Martini (2008).

TSI uses the current state and its derivatives to determine the next state by computing its Taylor Series described in Equation (6.1). The state vector is represented by \mathbf{X} with the corresponding vector for the initial conditions \mathbf{X}_0 . Each of the variables can at any point be represented by $x_n(t)$. For a given step-size h and an order $K \in \mathbb{R}$ (chosen by the user) the updated state $x_n(t+h)$ can be represented by the Taylor Series with $n = 1, \dots, 7$ in this case (7 variables: three position, three velocity and one mass). The exact solution is obtained by adding $T_{n,K}$, which is the truncation error for the n^{th} variable using K terms.

$$x_n(t+h) = \sum_{k=0}^K \frac{x_n^{(k)}(t)}{k!} (h)^k + T_{n,K} \quad (6.1)$$

This particular TSI method uses recurrence relations to determine the k^{th} order derivatives and only requires the current state (x_n) and its first derivatives ($x'_n = u_n$). Each recurrence relation describes a certain operation in the state derivative, such as: multiplication, division, power, exponential, sines and cosines. Equation (6.2) shows the recurrence relations for multiplication ($w(t) = f(t)g(t)$) and division ($w(t) = \frac{f(t)}{g(t)}$) respectively (the other operations are described later in this chapter when they are required).

$$\begin{aligned}
\text{For multiplications} \quad W(k) &= \sum_{j=0}^k F(j) G(k-j) \\
\text{For divisions} \quad W(k) &= \frac{1}{g(t_0)} \left[F(k) - \sum_{j=1}^k G(j) W(k-j) \right] \\
\text{Both with} \quad W(k) &= \frac{w^{(k)}(t_0)}{k!}, \quad F(j) = \frac{f^{(j)}(t_0)}{j!} \quad \text{and} \quad G(k-j) = \frac{g^{(k-j)}(t_0)}{(k-j)!}
\end{aligned} \tag{6.2}$$

Here, both $f(t)$ and $g(t)$ are place-holder functions and $w(t)$ is called the auxiliary function which replaces the respective operation. Sometimes, the state derivative functions can be rather complex and have many operations intertwined. One can then choose to introduce extra variables to simplify the derivatives and reduce the number of operations in that particular derivative. These extra variables together with the expression that they replace then form the auxiliary equations. A random example is shown in Equation (6.3).

$$\begin{aligned}
x_4' &= u_4 = 2x_1 + \frac{(x_3x_1 + x_2x_3)}{x_4} \\
x_8 &= x_3x_1 + x_2x_3
\end{aligned} \tag{6.3}$$

However, now that the extra variable x_8 is introduced, the derivative of the corresponding auxiliary equations has to be described as well (see Equation (6.4)), which in turn will use auxiliary functions to determine the k^{th} derivative of x_8 .

$$\begin{aligned}
x_4' &= u_4 = 2x_1 + \frac{x_8}{x_4} \\
x_8' &= u_8 = x_3'x_1 + x_3x_1' + x_2'x_3 + x_2x_3' = u_3x_1 + x_3u_1 + u_2x_3 + x_2u_3
\end{aligned} \tag{6.4}$$

At this point it should be emphasised that using auxiliary equations and derivatives is a choice. It is not required to make TSI work. Sometimes it can be easier to introduce auxiliary equations because it makes the problem more comprehensible but this could introduce errors because all auxiliary equations also require auxiliary derivatives, which might not be easy to find. In those cases it could be more useful to just leave the state derivatives as they are and write more auxiliary functions instead. This all depends on the problem and the preference of the user.

Now let $u_n^{(k-1)} = x_n^k$ for $k = 1, \dots, K$, then $\frac{u_n^{(k-1)}}{(k-1)!} = \frac{x_n^k}{(k-1)!}$, and also $\frac{x_n^k}{k!} = X_n(k)$. Combining this results in Equation (6.5).

$$U_n(k-1) = kX_n(k) \Rightarrow X_n(k) = \frac{U_n(k-1)}{k} \tag{6.5}$$

The $X_n(k)$ are also known as the Taylor Series coefficients of the n^{th} variable for the k^{th} order derivative. Also, $U_n(k)$ are the recurrence relation expressions for the n^{th} variable which consist of all the reduced auxiliary functions ($W(k)$) that form that derivative.

Using the expression described in Equation (6.5) all Taylor Series coefficients can be found. Then Equation (6.1) can be used to determine the next state values at time $t+h$ for the known previous parameter values at time t . The same can then be done to determine the values at the time-step after that using the state values at $t+h$, etc. Going through all these different time-steps results in the final integration.

6.1.2. STEP-SIZE

The step-size used for TSI can be either set as a constant value by the user or determined using a step-size controller, giving it the variable step-size properties, which is done in this thesis. The chosen step-size method was based on the recommendation of both Scott and Martini (2008) and Bergsma (2015) and directly uses the chosen (or preferred) local error tolerance τ to determine the next step size. This method assures that the step-size is small enough such that all variables satisfy the error condition directly. The step-size is determined using a so-called fixed-point iteration performed using Equation (6.6). The initial step-size h_1 can be

chosen to be the current step-size h as an easy estimate. Then the iteration is performed over l until a certain required convergence is reached.

$$h_{l+1} = \exp\left(\frac{1}{K-1} \ln\left[\frac{\tau}{|X_n(K-1)| + K|X_n(K)|h_l}\right]\right) \quad (6.6)$$

This is then done for all variables and the smallest required step-size is chosen, which is then used to determine the next step-size through $h_{next} = \eta h_{chosen}$, where η is the chosen step multiplication factor which has to be smaller than 1.

6.2. ASSOCIATED EQUATIONS

In order for TSI to be implemented, the state derivatives have to be modelled as a set of continuous functions which are a function of the state only. This can be done in different ways. In this case, three cases were tested: two Cartesian cases and one spherical case. For the Cartesian cases, the initial conditions first have to be transformed into Cartesian coordinates. The Cartesian equations themselves require reference frame transformations, which can be written in two different ways. The first case is described in Section 6.2.1 and the second in Section 6.2.2. The reason for testing the spherical case is that the initial conditions are provided in spherical coordinates and the intermediate computations can be easily interpreted and checked for errors. However, the equations are highly sensitive to singularities. The spherical equations are described in Section 6.2.3 and already include reference frame transformations.

6.2.1. CARTESIAN EQUATIONS, FIRST CASE

The Cartesian state is described in Equation (6.7), where m_{MAV} is the mass of the MAV and the subscript I refers to the inertial frame.

$$\mathbf{r} = \begin{pmatrix} x_I \\ y_I \\ z_I \end{pmatrix} \quad \mathbf{V} = \begin{pmatrix} V_{x_I} \\ V_{y_I} \\ V_{z_I} \end{pmatrix} \quad m_{MAV} \quad (6.7)$$

The corresponding state derivatives are then described by Equation (6.8).

$$\begin{aligned} \dot{x}_I &= V_{x_I} & \ddot{x}_I &= \dot{V}_{x_I} = a_{x_I} \\ \dot{y}_I &= V_{y_I} & \ddot{y}_I &= \dot{V}_{y_I} = a_{y_I} \\ \dot{z}_I &= V_{z_I} & \ddot{z}_I &= \dot{V}_{z_I} = a_{z_I} \end{aligned} \quad \dot{m}_{MAV} = -\frac{T}{g_0 I_{sp}} \quad (6.8)$$

From this point on, the subscript I is omitted, because the state and the state derivatives are always presented in the inertial frame. If variables have to be presented in any other reference frame the corresponding subscripts will be provided and explained. The accelerations in the x-, y- and z-direction have three contributing components: gravitational acceleration, drag and thrust. The gravitational acceleration can be directly expressed in the inertial frame, however the drag is presented in the body frame and the thrust is expressed in the propulsion frame. Therefore, both the drag and thrust contributions have to be transformed to the inertial frame using transformation matrices. This then results in the expression for the acceleration vector as shown by Equation (6.9). The subscript G shows that the parameter is a function of the ground velocity.

$$\begin{aligned} \begin{pmatrix} a_x \\ a_y \\ a_z \end{pmatrix} &= \begin{pmatrix} -\mu_M \frac{x}{r^3} \\ -\mu_M \frac{y}{r^3} \\ -\mu_M \frac{z}{r^3} \end{pmatrix} + \left| \mathbb{T}_Z(-\Omega_M t_O + \omega_P) \right|_{\mathbf{I}} \left| \mathbb{T}_Z(-\tau) \mathbb{T}_Y\left(\frac{\pi}{2} + \delta\right) \right|_{\mathbf{V}} \left| \mathbb{T}_Z(-\chi_G) \mathbb{T}_Y(-\gamma_G) \right|_{\mathbf{B}} \left[\begin{pmatrix} -\frac{D}{m_{MAV}} \\ 0 \\ 0 \end{pmatrix} + \dots \right. \\ &\quad \left. \dots \left| \mathbb{T}_Z(-\psi_T) \mathbb{T}_Y(-\epsilon_T) \right|_{\mathbf{P}} \left[\begin{pmatrix} \frac{T}{m_{MAV}} \\ 0 \\ 0 \end{pmatrix} \right] \right] \quad (6.9) \end{aligned}$$

It can be seen that this set of equations is a function of the current position and many other parameters. These parameters will all have to be written as a function of the current state. This can be done by writing them into auxiliary equations, forming extra variables that then also require the auxiliary derivatives. This works for certain parameters, such as the gravity, because these equations are already expressed in the inertial frame. However, the transformation angles are defined in different reference frames, which means that finding the proper auxiliary derivatives can be tricky sometimes. Therefore it was decided to directly write these parameters as auxiliary functions. Each of the auxiliary functions performs one simple algebraic operation and the collection of these auxiliary functions then form the complete set of recurrence relations using the recurrence relations for the simple algebraic operations. For the auxiliary equations, a similar notation will be used as shown by [Scott and Martini \(2008\)](#). Here the equations are denoted by x_{number} and the corresponding derivatives x'_{number} . This notation will also be used for the current state and the corresponding state derivatives. This way, Equation (6.7) can be written as Equation (6.10) and the corresponding derivatives can be written as presented by Equation (6.11).

$$\begin{aligned} x_1 &= x & x_4 &= \dot{x} = V_x & x_7 &= m_{MAV} \\ x_2 &= y & x_5 &= \dot{y} = V_y & & \\ x_3 &= z & x_6 &= \dot{z} = V_z & & \end{aligned} \quad (6.10)$$

$$\begin{aligned} x'_1 &= x_4 & x'_4 &= \dot{V}_x = a_x = a_{g,x} + a_{D,x} + a_{T,x} & x'_7 &= \dot{m}_{MAV} = -\frac{T}{g_0 I_{sp}} \\ x'_2 &= x_5 & x'_5 &= \dot{V}_y = a_y = a_{g,y} + a_{D,y} + a_{T,y} & & \\ x'_3 &= x_6 & x'_6 &= \dot{V}_z = a_z = a_{g,z} + a_{D,z} + a_{T,z} & & \end{aligned} \quad (6.11)$$

In this case the thrust and specific impulse are constant, which means that x'_7 is constant and any additional derivative will be zero. Also, neither one of the thrust angles is a function of the state, which means that a_T , in the body frame, is only a function of x_7 (also see Equation (6.9)). However, both a_g and a_D are a function of the position and velocity, where a_D is also a function of the MAV mass. Only a_g is rewritten using auxiliary equations as mentioned before.

GRAVITATIONAL ACCELERATION

For the gravitational acceleration two auxiliary equations were required since $r = \sqrt{x^2 + y^2 + z^2}$. The resulting expressions for the gravitational acceleration are shown in Equation (6.12) with the corresponding auxiliary equations and the derivatives defined in Equation (6.13).

$$\begin{aligned} a_{g,x} &= -\mu_M \frac{x_1}{r^3} = \frac{x_1}{(x_1^2 + x_2^2 + x_3^2)^{3/2}} = -\mu_M \frac{x_1}{x_9} \\ a_{g,y} &= -\mu_M \frac{x_2}{r^3} = \frac{x_2}{(x_1^2 + x_2^2 + x_3^2)^{3/2}} = -\mu_M \frac{x_2}{x_9} \\ a_{g,z} &= -\mu_M \frac{x_3}{r^3} = \frac{x_3}{(x_1^2 + x_2^2 + x_3^2)^{3/2}} = -\mu_M \frac{x_3}{x_9} \end{aligned} \quad (6.12)$$

$$\begin{aligned} x_8 &= x_1^2 + x_2^2 + x_3^2 & x'_8 &= 2x_1x_4 + 2x_2x_5 + 2x_3x_6 \\ x_9 &= x_8^{3/2} & x'_9 &= \frac{3}{2} \frac{x_9x'_8}{x_8} \end{aligned} \quad (6.13)$$

TRANSFORMATION ANGLES

The angles required for the transformation to go from the body frame to the reference frame all have to be written as a function of the state variables. The required angles are λ , δ , χ_G and γ_G . Here $\lambda = \tau + \Omega_M t_O - \omega_P$. This means that instead of first transforming to the rotating frame completely and then transforming to the inertial frame, an inertial longitude angle λ can be defined to directly transform to the inertial frame. The first two angles are the longitude and latitude and are spherical coordinates. Thus the relations for these angles can be found using the transformation from the Cartesian to the spherical system. However, the angles themselves are not required directly, because they are only used in transformation matrices. These matrices

Figure 6.1: Spherical position variables in an inertial Cartesian frame (Noomen, 2013).

are comprised of the sines and cosines of these angles, which means that a direct relation between the state variables and the sines and cosines of the position angles can be used. These relations can be derived from Figure 6.1 and are described in Equation (6.14)

$$\begin{aligned}
 r &= \sqrt{x^2 + y^2 + z^2} & \sin \lambda &= \frac{y}{\sqrt{x^2 + y^2}} & \sin \delta &= \frac{z}{r} \\
 & & \cos \lambda &= \frac{x}{\sqrt{x^2 + y^2}} & \cos \delta &= \frac{\sqrt{x^2 + y^2}}{r}
 \end{aligned} \tag{6.14}$$

The corresponding auxiliary functions can then be described by Equation (6.15) using the definitions provided in Equations (6.10) and (6.11).

$$\begin{aligned}
 w_{4,1} &= x_1^2 + x_2^2 & w_{4,5} &= s\lambda = \frac{x_2}{w_{4,4}} & w_{4,7} &= s\delta = \frac{x_3}{w_{4,3}} \\
 w_{4,2} &= w_{4,1} + x_3^2 & & & & & \\
 w_{4,3} &= r = \sqrt{w_{4,2}} & w_{4,6} &= c\lambda = \frac{x_1}{w_{4,4}} & w_{4,8} &= c\delta = \frac{w_{4,4}}{w_{4,3}} \\
 w_{4,4} &= \sqrt{w_{4,1}} & & & & &
 \end{aligned} \tag{6.15}$$

The latitude and longitude could be described using the position vector in the inertial frame, however the transformation from the body frame to the vertical frame is a function of the ground (underscore 'G') velocity in the rotational frame. Since the position and velocity in the inertial frame are known (current state), the ground velocity (V_G) can be written as a function of the inertial velocity (V_I). For this, the velocity components have to be transformed from the inertial frame to the vertical frame (which is the inverse of the first

three transformations described in Equation (6.9)). This transformation is shown in Equation (6.16) and was described in Mooij (1994). Here, c stands for cosine and s stands for sine. This transformation also includes the rotational effect on the velocity due to the rotation of Mars.

$$\mathbf{V}_V = \begin{pmatrix} V_{x_V} \\ V_{y_V} \\ V_{z_V} \end{pmatrix} = \begin{bmatrix} -c\lambda s\delta & -s\lambda s\delta & c\delta \\ -s\lambda & c\lambda & 0 \\ -c\lambda c\delta & -s\lambda c\delta & -s\delta \end{bmatrix} \left\{ \begin{pmatrix} V_x \\ V_y \\ V_z \end{pmatrix} - \begin{pmatrix} 0 \\ 0 \\ \Omega_M \end{pmatrix} \times \begin{pmatrix} x \\ y \\ z \end{pmatrix} \right\} \quad (6.16)$$

The ground velocity can now be computed as the norm of the vertical velocity vector as shown by Equation (6.17). The transformation matrices disappear because the norm of a transformation matrix is simply 1, which means that $V_G = V_V = V_R$.

$$V_G = \|\mathbf{V}_V\| = \left\| \begin{pmatrix} V_x \\ V_y \\ V_z \end{pmatrix} - \begin{pmatrix} 0 \\ 0 \\ \Omega_M \end{pmatrix} \times \begin{pmatrix} x \\ y \\ z \end{pmatrix} \right\| \quad (6.17)$$

Equation (6.17) can be rewritten as Equation (6.18).

$$V_G = \sqrt{(V_x + \Omega_M y)^2 + (V_y - \Omega_M x)^2 + V_z^2} \quad (6.18)$$

The corresponding auxiliary functions are provided in Equation (6.19).

$$\begin{aligned} w_{4,9} &= V_x + \Omega_M y = x_4 + \Omega_M x_2 & w_{4,11} &= w_{4,9}^2 + w_{4,10}^2 + x_6^2 \\ w_{4,10} &= V_y - \Omega_M x = x_5 - \Omega_M x_1 & w_{4,12} &= V_G = \sqrt{w_{4,11}} \end{aligned} \quad (6.19)$$

The spherical velocity angles can now be derived from Figure 6.2 as described by Equation (6.20). These were also provided by Mooij (1994).

Figure 6.2: Spherical velocity variables in a vertical Cartesian frame (Mooij, 1994).

$$\begin{aligned} \sin \chi_G &= \frac{V_{y_V}}{\sqrt{V_{x_V}^2 + V_{y_V}^2}} & \sin \gamma_G &= \frac{-V_{z_V}}{V_G} \\ \cos \chi_G &= \frac{V_{x_V}}{\sqrt{V_{x_V}^2 + V_{y_V}^2}} & \cos \gamma_G &= \frac{\sqrt{V_{x_V}^2 + V_{y_V}^2}}{V_G} \end{aligned} \quad (6.20)$$

Here, V_{x_V} , V_{y_V} and V_{z_V} are the velocities in the vertical frame. Expressions for these variables can be obtained by rewriting Equation (6.16). This then results in Equation (6.22).

$$\begin{aligned} V_{x_V} &= -(V_x + \Omega_M y) s \delta c \lambda - (V_y - \Omega_M x) s \delta s \lambda + V_z c \delta \\ V_{y_V} &= (V_y - \Omega_M x) c \lambda - (V_x + \Omega_M y) s \lambda \\ V_{z_V} &= -(V_x + \Omega_M y) c \delta c \lambda - (V_y - \Omega_M x) c \delta s \lambda - V_z s \delta \end{aligned} \quad (6.21)$$

The combined auxiliary functions for Equations (6.20) and (6.22) are described in Equation (6.19).

$$\begin{aligned} w_{4,13} &= -c \lambda s \delta = -w_{4,6} w_{4,7} & w_{4,17} &= V_{x_V} = x_6 w_{4,8} + w_{4,9} w_{4,13} + w_{4,10} w_{4,14} & w_{4,22} &= s \chi_G = \frac{w_{4,18}}{w_{4,21}} \\ w_{4,14} &= -s \delta s \lambda = -w_{4,7} w_{4,5} & w_{4,18} &= V_{y_V} = w_{4,10} w_{4,6} - w_{4,9} w_{4,5} & w_{4,23} &= c \chi_G = \frac{w_{4,17}}{w_{4,21}} \\ w_{4,15} &= -c \delta c \lambda = -w_{4,8} w_{4,6} & w_{4,19} &= V_{z_V} = w_{4,9} w_{4,15} - x_6 w_{4,7} + w_{4,10} w_{4,16} & w_{4,24} &= s \gamma_G = -\frac{w_{4,19}}{w_{4,12}} \\ w_{4,16} &= -c \delta s \lambda = w_{4,8} w_{4,5} & w_{4,20} &= V_{x_V}^2 + V_{y_V}^2 = w_{4,17}^2 + w_{4,18}^2 & w_{4,25} &= c \gamma_G = \frac{w_{4,21}}{w_{4,12}} \\ & & w_{4,21} &= \sqrt{w_{4,20}} \end{aligned} \quad (6.22)$$

DRAG ACCELERATION

The drag acceleration is determined in the body frame by dividing the drag force (D) by the mass of the MAV (x_7). The drag force itself is a function of the position and velocity. The equations associated with the drag function are described in Equation (6.23) except for the C_D equations. The polynomial coefficients for the density equation are provided in Table 3.4 and are represented in Equation (6.23) by P_ρ .

$$\begin{aligned} h &= r - R_{MOLA} \\ D &= \frac{1}{2} \rho V_G^2 S C_D \\ \rho &= e^{P_{\rho 10} h^{10} + P_{\rho 9} h^9 + P_{\rho 8} h^8 + P_{\rho 7} h^7 + P_{\rho 6} h^6 + P_{\rho 5} h^5 + P_{\rho 4} h^4 + P_{\rho 3} h^3 + P_{\rho 2} h^2 + P_{\rho 1} h + P_{\rho 0}} \end{aligned} \quad (6.23)$$

The numbering for the drag auxiliary functions start with 27 because it was added later on and because it used to be an auxiliary equation. The auxiliary functions for the density can then be described by Equation (6.29).

$$\begin{aligned} w_{27,1} &= h = w_{4,3} - R_{MOLA} & w_{27,7} &= w_{27,1}^7 \\ w_{27,2} &= w_{27,1}^2 & w_{27,8} &= w_{27,1}^8 \\ w_{27,3} &= w_{27,1}^3 & w_{27,9} &= w_{27,1}^9 \\ w_{27,4} &= w_{27,1}^4 & w_{27,10} &= w_{27,1}^{10} \\ w_{27,5} &= w_{27,1}^5 & w_{27,11} &= P_{\rho 10} w_{27,10} + P_{\rho 9} w_{27,9} + \dots + P_{\rho 1} w_{27,1} + P_{\rho 0} \\ w_{27,6} &= w_{27,1}^6 & w_{27,12} &= \rho = e^{w_{27,11}} \end{aligned} \quad (6.24)$$

Since the drag coefficient is a function of Mach number as by Figure 3.8 and is not a continuous function, it has to be split into 6 different sections. Each section has a separate $C_D - M$ relation. Before these relations can be described, three additional expressions are required which are described in Equation (6.25).

$$\begin{aligned} M &= \frac{V_G}{a} \\ a &= \sqrt{\gamma_a R_a^* T_a} \quad \text{where} \quad R_a^* = \frac{R_a}{M_a} \end{aligned} \quad (6.25)$$

Where the corresponding auxiliary functions can be described by Equation (6.26).

$$\begin{aligned}
w_{27,14} &= a = \sqrt{\gamma_a R_a^* w_{27,13}} \\
w_{27,15} &= M = \frac{w_{4,12}}{w_{27,14}}
\end{aligned} \tag{6.26}$$

The conditional relations shown in Equation (6.27) describe the different equations that have to be used associated with the different sections of the drag coefficient plot. Here $P_{C_D \text{ number, section}}$ are the polynomial fit coefficients as provided in Table 3.5.

$$C_D = \begin{cases} 0.2, & \text{for } 0 \leq M < 0.5 \\ P_{C_D 1,2} M + P_{C_D 0,2}, & \text{for } 0.5 \leq M < 1 \\ P_{C_D 1,3} M + P_{C_D 0,3}, & \text{for } 1 \leq M < 1.3 \\ P_{C_D 1,4} M + P_{C_D 0,4}, & \text{for } 1.3 \leq M < 2.5 \\ P_{C_D 1,5} M + P_{C_D 0,5}, & \text{for } 2.5 \leq M < 4 \\ 0.3, & \text{for } M \geq 4 \end{cases} \tag{6.27}$$

In this case, the auxiliary functions for $C_D (= w_{27,16})$ is any of the conditional relations depending on $M (= w_{27,15})$.

This only leaves the temperature $T_a (= w_{27,13})$, which is a function of the altitude $h (= w_{27,1})$ in km, [MOLA](#). But as described in Section 3.4.1, this parameter is split into different sections as well. The equations per section for the temperature is provided in Equation (6.28). Here $P_{T \text{ number, section}}$ are the polynomial fit coefficients as provided in Table 3.2.

$$T_a = \begin{cases} P_{T1,1} h + P_{T0,1}, & \text{for } -0.6 \leq h < 5.04 \\ P_{T3,2} h^3 + P_{T2,2} h^2 + P_{T1,2} h + P_{T0,2}, & \text{for } 5.04 \leq h < 35.53 \\ P_{T6,3} h^6 + P_{T5,3} h^5 + P_{T4,3} h^4 + P_{T3,3} h^3 + \dots \\ \quad \dots + P_{T2,3} h^2 + P_{T1,3} h + P_{T0,3}, & \text{for } 35.53 \leq h < 75.07 \\ P_{T8,4} h^8 + P_{T7,4} h^7 + P_{T6,4} h^6 + P_{T5,4} h^5 + \dots \\ \quad \dots + P_{T4,4} h^4 + P_{T3,4} h^3 + P_{T2,4} h^2 + P_{T1,4} h + P_{T0,4}, & \text{for } 75.07 \leq h < 170.05 \\ 136.5, & \text{for } h \geq 170.05 \end{cases} \tag{6.28}$$

For both the conditional parameters C_D and T_a the required section has to be determined before the evaluation of the equations.

The drag can now also be described as an auxiliary function as shown by Equation (6.29).

$$\begin{aligned}
w_{27,17} &= V_G^2 = w_{4,12}^2 \\
w_{27,18} &= V_G^2 C_D = w_{27,17} w_{27,16} \\
w_{27,19} &= D = \frac{1}{2} S w_{27,18} w_{27,12}
\end{aligned} \tag{6.29}$$

THRUST ACCELERATION

The only acceleration component still missing is the thrust acceleration. To be able to write the auxiliary functions for the thrust, Equation (6.9) first has to be rewritten such that all the transformations are gathered into two transformation matrices (see Equation (6.30)). The transformation matrices are described by Equations (6.31) and (6.32) for \mathbb{T}_{BP} and \mathbb{T}_{IB} respectively.

$$\begin{pmatrix} x'_4 \\ x'_5 \\ x'_6 \end{pmatrix} = \begin{pmatrix} -\mu_M \frac{x_1}{x_9} \\ -\mu_M \frac{x_2}{x_9} \\ -\mu_M \frac{x_3}{x_9} \end{pmatrix} + \mathbb{T}_{\text{IB}} \left[\begin{pmatrix} -\frac{w_{27,19}}{x_7} \\ 0 \\ 0 \end{pmatrix} + \mathbb{T}_{\text{BP}} \begin{pmatrix} T \\ x_7 \\ 0 \\ 0 \end{pmatrix} \right] \tag{6.30}$$

$$\mathbb{T}_{\text{BP}} = \begin{bmatrix} c\psi_T c\epsilon_T & -s\psi_T & c\psi_T s\epsilon_T \\ s\psi_T c\epsilon_T & c\psi_T & s\psi_T s\epsilon_T \\ -s\epsilon_T & 0 & c\epsilon_T \end{bmatrix} \tag{6.31}$$

$$\mathbb{T}_{\mathbf{IB}} = \begin{bmatrix} c\lambda(-s\delta c\chi c\gamma + c\delta s\gamma) - s\lambda s\chi c\gamma & c\lambda s\delta s\chi - s\lambda c\chi & c\lambda(-s\delta c\chi s\gamma - c\delta c\gamma) - s\lambda s\chi s\gamma \\ s\lambda(-s\delta c\chi c\gamma + c\delta s\gamma) + c\lambda s\chi c\gamma & s\lambda s\delta s\chi + c\lambda c\chi & s\lambda(-s\delta c\chi s\gamma - c\delta c\gamma) + c\lambda s\chi s\gamma \\ c\delta c\chi c\gamma + s\delta s\gamma & -c\delta s\chi & c\delta c\chi s\gamma - s\delta c\gamma \end{bmatrix} \quad (6.32)$$

The thrust accelerations in the x-, y- and z-directions (in the body frame) can now be found by rewriting the last part of Equation (6.30) to Equation (6.33) using Equation (6.31).

$$\mathbb{T}_{\mathbf{BP}} \begin{pmatrix} T \\ \frac{x_7}{T} \\ 0 \\ 0 \end{pmatrix} = \begin{pmatrix} \frac{T}{x_7} c\psi_T c\epsilon_T \\ \frac{T}{x_7} s\psi_T c\epsilon_T \\ \frac{T}{x_7} \\ -\frac{T}{x_7} s\epsilon_T \end{pmatrix} \quad (6.33)$$

Equation (6.33) can be expressed as a collection of auxiliary functions as well. These are described in Equation (6.34).

$$\begin{aligned} w_{4,26} &= \cos \psi_T & w_{4,33} &= \frac{T}{x_7} = T w_{4,32} \\ w_{4,27} &= \cos \epsilon_T & w_{4,34} &= \frac{T}{x_7} c\epsilon_T c\psi_T = w_{4,33} w_{4,30} \\ w_{4,28} &= \sin \psi_T & w_{4,37} &= \frac{T}{x_7} c\epsilon_T s\psi_T = w_{4,33} w_{4,31} \\ w_{4,29} &= \sin \epsilon_T & w_{4,38} &= \frac{T}{x_7} s\epsilon_T = w_{4,33} w_{4,29} \\ w_{4,30} &= c\psi_T c\epsilon_T = w_{4,26} w_{4,27} \\ w_{4,31} &= c\epsilon_T s\psi_T = w_{4,27} w_{4,28} \\ w_{4,32} &= \frac{1}{x_7} \end{aligned} \quad (6.34)$$

The thrust accelerations are now written in the body frame, which means that they can be combined with the drag acceleration in the body frame. This is done in Equation (6.35). Here, $w_{4,35}$ represents the drag acceleration in the body frame and $w_{4,36}$ is the total acceleration in the x-direction in the body frame caused by both the drag and the thrust.

$$\begin{pmatrix} -\frac{x_{27}}{x_7} \\ \frac{x_7}{T} \\ 0 \\ 0 \end{pmatrix} + \begin{pmatrix} w_{4,34} \\ w_{4,37} \\ -w_{4,38} \end{pmatrix} = \begin{pmatrix} w_{4,34} - w_{4,35} \\ w_{4,37} \\ -w_{4,38} \end{pmatrix} = \begin{pmatrix} w_{4,36} \\ w_{4,37} \\ -w_{4,38} \end{pmatrix} \quad (6.35)$$

ALL ACCELERATIONS COMBINED

At this point the gravity accelerations are known in the inertial frame and the drag and thrust accelerations in the body frame. In order to get the final acceleration vector in the inertial frame, the drag and thrust accelerations have to be transformed from the body frame to the inertial frame using $\mathbb{T}_{\mathbf{IB}}$ resulting in Equation (6.36).

$$\mathbb{T}_{\mathbf{IB}} \begin{pmatrix} w_{4,36} \\ w_{4,37} \\ -w_{4,38} \end{pmatrix} = \begin{pmatrix} w_{4,36} (c\lambda(-s\delta c\chi c\gamma + c\delta s\gamma) - s\lambda s\chi c\gamma) + w_{4,37} (c\lambda s\delta s\chi - s\lambda c\chi) - w_{4,38} (c\lambda(-s\delta c\chi s\gamma - c\delta c\gamma) - s\lambda s\chi s\gamma) \\ w_{4,36} (s\lambda(-s\delta c\chi c\gamma + c\delta s\gamma) + c\lambda s\chi c\gamma) + w_{4,37} (s\lambda s\delta s\chi + c\lambda c\chi) - w_{4,38} (s\lambda(-s\delta c\chi s\gamma - c\delta c\gamma) + c\lambda s\chi s\gamma) \\ w_{4,36} (c\delta c\chi c\gamma + s\delta s\gamma) + w_{4,37} (-c\delta s\chi) - w_{4,38} (c\delta c\chi s\gamma - s\delta c\gamma) \end{pmatrix} \quad (6.36)$$

Now including the gravity components as well, the (lengthy) expressions for x'_4 , x'_5 and x'_6 become Equations (6.37) to (6.39) respectively.

$$\begin{aligned} x'_4 &= -\mu_M \frac{x_1}{x_9} + w_{4,36} (c\lambda(-s\delta c\chi c\gamma + c\delta s\gamma) - s\lambda s\chi c\gamma) + \dots \\ &\quad \dots w_{4,37} (c\lambda s\delta s\chi - s\lambda c\chi) - \dots \\ &\quad \dots w_{4,38} (c\lambda(-s\delta c\chi s\gamma - c\delta c\gamma) - s\lambda s\chi s\gamma) \end{aligned} \quad (6.37)$$

$$\begin{aligned}
x'_5 = & -\mu_M \frac{x_2}{x_9} + w_{4,36} (s\lambda (-s\delta c\chi\gamma + c\delta s\gamma) + c\lambda s\chi\gamma) + \dots \\
& \dots w_{4,37} (s\lambda s\delta s\chi + c\lambda c\chi) - \dots \\
& \dots w_{4,38} (s\lambda (-s\delta c\chi s\gamma - c\delta c\gamma) + c\lambda s\chi s\gamma)
\end{aligned} \tag{6.38}$$

$$x'_6 = -\mu_M \frac{x_3}{x_9} + w_{4,36} (c\delta c\chi\gamma + s\delta s\gamma) + w_{4,37} (-c\delta s\chi) - w_{4,38} (c\delta c\chi s\gamma - s\delta c\gamma) \tag{6.39}$$

These equations now have to be written as a collection of auxiliary functions for the x-, y- and z-direction in the inertial frame. The gravitational acceleration can be written as the vector shown by Equation (6.40).

$$\mathbf{a_g} = \begin{pmatrix} -\mu_M \frac{x_1}{x_9} \\ -\mu_M \frac{x_2}{x_9} \\ -\mu_M \frac{x_3}{x_9} \end{pmatrix} = \begin{pmatrix} w_{4,39} \\ w_{5,1} \\ w_{6,1} \end{pmatrix} \tag{6.40}$$

The auxiliary derivatives ($u = x'$) can now be defined as the collection of auxiliary functions that describe the different transformations for u_4, u_5 and u_6 . These are shown in Equations (6.41) to (6.43) respectively.

$$\begin{aligned}
w_{4,40} &= -s\delta c\chi_G = -w_{4,7} w_{4,23} & w_{4,46} &= w_{4,42} c\gamma_G = w_{4,42} w_{4,25} \\
w_{4,41} &= c\delta s\gamma_G = w_{4,8} w_{4,24} & w_{4,47} &= -w_{4,13} s\chi_G = -w_{4,13} w_{4,22} \\
w_{4,42} &= -s\lambda s\chi_G = -w_{4,5} w_{4,22} & w_{4,48} &= w_{4,40} s\gamma_G = w_{4,40} w_{4,24} \\
w_{4,43} &= -s\lambda c\chi_G = -w_{4,5} w_{4,23} & w_{4,49} &= w_{4,42} s\gamma_G = w_{4,42} w_{4,24} \\
w_{4,44} &= -c\delta c\gamma_G = -w_{4,8} w_{4,25} & w_{4,50} &= c\lambda (w_{4,45} + w_{4,41}) + w_{4,46} = w_{4,6} (w_{4,45} + w_{4,41}) + w_{4,46} \\
w_{4,45} &= w_{4,40} c\gamma_G = w_{4,40} w_{4,25} & w_{4,51} &= c\lambda (w_{4,48} + w_{4,44}) + w_{4,49} = w_{4,6} (w_{4,48} + w_{4,44}) + w_{4,49} \\
& & w_{4,52} &= w_{4,39} + w_{4,36} w_{4,50} + w_{4,37} (w_{4,47} + w_{4,43}) - w_{4,38} w_{4,51} \\
& & u_4 &= w_{4,52}
\end{aligned} \tag{6.41}$$

$$\begin{aligned}
w_{5,2} &= c\lambda s\chi_G = w_{4,6} w_{4,22} \\
w_{5,3} &= s\lambda (w_{4,45} + w_{4,41}) + w_{5,2} c\gamma_G = w_{4,5} (w_{4,45} + w_{4,41}) + w_{5,2} w_{4,25} \\
w_{5,4} &= -w_{4,14} s\chi_G + c\lambda c\chi_G = -w_{4,14} w_{4,22} + w_{4,6} w_{4,23} \\
w_{5,5} &= s\lambda (w_{4,48} + w_{4,44}) + w_{5,2} s\gamma_G = w_{4,5} (w_{4,48} + w_{4,44}) + w_{5,2} w_{4,24} \\
w_{5,6} &= w_{5,1} + w_{4,36} w_{5,3} + w_{4,37} w_{5,4} - w_{4,38} w_{5,5} \\
u_5 &= w_{5,6}
\end{aligned} \tag{6.42}$$

$$\begin{aligned}
w_{6,2} &= s\delta s\gamma_G = w_{4,7} w_{4,24} & w_{6,5} &= -w_{4,44} c\chi_G + w_{6,2} = -w_{4,44} w_{4,23} + w_{6,2} \\
w_{6,3} &= c\delta s\chi_G = w_{4,8} w_{4,22} & w_{6,6} &= w_{4,41} c\chi_G + w_{6,4} = w_{4,41} w_{4,23} + w_{6,4} \\
w_{6,4} &= -s\delta c\gamma_G = -w_{4,7} w_{4,25} & w_{6,7} &= w_{6,1} + w_{4,36} w_{6,5} - w_{4,37} w_{6,3} - w_{4,38} w_{6,6} \\
& & u_6 &= w_{6,7}
\end{aligned} \tag{6.43}$$

Also, because auxiliary equations were used for the gravitational acceleration. The corresponding auxiliary derivatives can be written as a collection of auxiliary functions as shown in Equation (6.44).

$$\begin{aligned}
w_{8,1} &= x_1 x_4 & w_{9,0} &= x_9 u_8 \\
w_{8,2} &= x_2 x_5 & w_{9,1} &= \frac{w_{9,0}}{x_8} \\
w_{8,3} &= x_3 x_6 & u_9 &= 1.5 w_{9,1} \\
u_8 &= 2 (w_{8,1} + w_{8,2} + w_{8,3})
\end{aligned} \tag{6.44}$$

Then the equations in Equation (6.45) complete the whole set of auxiliary derivatives.

$$\begin{aligned} u_1 &= x_4 & u_3 &= x_6 \\ u_2 &= x_5 & u_7 &= -\frac{T}{g_0 I_{sp}} \end{aligned} \quad (6.45)$$

6.2.2. CARTESIAN EQUATIONS, SECOND CASE

The second case (based on a method described by (Bergsma, 2015)) is similar to the first case in terms of set-up of the dynamic equations, the gravitational acceleration, and the drag and thrust accelerations in the body frame. The only difference lies in the formulation of $\mathbb{T}_{\mathbf{IB}}$. Instead of using Euler angles and rotation transformation matrices, $\mathbb{T}_{\mathbf{IB}}$ can be set-up as one single matrix performing a direct transformation. This matrix is described in Equation (6.46), where C stands for transformation matrix coefficient.

$$\mathbb{T}_{\mathbf{IB}} = \begin{bmatrix} C_1 & C_4 & C_7 \\ C_2 & C_5 & C_8 \\ C_3 & C_6 & C_9 \end{bmatrix} \quad (6.46)$$

As was seen in Section 6.2.1 the rotation from the vertical to the inertial frame is purely a function of the radius in the inertial frame (\mathbf{r} or $\mathbf{r}_{\mathbf{I}}$). Also, the transformation from the body frame to the vertical frame was purely a function of the ground velocity in the vertical frame ($\mathbf{V}_{\mathbf{V}}$ or $\mathbf{V}_{\mathbf{G}_{\mathbf{V}}}$). Therefore, if this transformation is to be done in one transformation, the ground velocity in the inertial frame is required ($\mathbf{V}_{\mathbf{G}_{\mathbf{I}}}$), because it would transform directly to the inertial frame. This means that the coefficients in Equation (6.46) will have to be a function of $\mathbf{r}_{\mathbf{I}}$ and $\mathbf{V}_{\mathbf{G}_{\mathbf{I}}}$, where $\mathbf{V}_{\mathbf{G}_{\mathbf{I}}}$ is given by Equation (6.47).

$$\mathbf{V}_{\mathbf{G}_{\mathbf{I}}} = \begin{pmatrix} V_x \\ V_y \\ V_z \end{pmatrix} - \begin{pmatrix} 0 \\ 0 \\ \Omega_M \end{pmatrix} \times \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} V_x + \Omega_M y \\ V_y - \Omega_M x \\ V_z \end{pmatrix} \quad (6.47)$$

BODY FRAME UNIT VECTORS

So when looking from the inertial frame, there are two state vectors: position and ground velocity. The state changes part due to the accelerations in the body frame $\mathbf{a}_{\mathbf{B}}$, which is a vector comprised of the drag and thrust accelerations. This vector has the same length and direction in the body frame and the inertial frame. Also, any vector is simply a multiplication of the corresponding unit vector. The same holds for the velocity, which means that because the velocity in the body frame is defined through the x-axis of that frame, the unit vector of the ground velocity can be described as the unit vector in the x-direction $\hat{\mathbf{i}}$ as shown by Equation (6.48).

$$\hat{\mathbf{i}} = \frac{\mathbf{V}_{\mathbf{G}_{\mathbf{I}}}}{\|\mathbf{V}_{\mathbf{G}_{\mathbf{I}}}\|} \quad (6.48)$$

This unit vector is also shown in Figure 6.3.

In Figure 6.3 it can be seen that the z-axis unit vector $\hat{\mathbf{k}}$ is defined in the same plane as $\hat{\mathbf{i}}$, $\mathbf{V}_{\mathbf{G}_{\mathbf{I}}}$ and $\mathbf{r}_{\mathbf{I}}$ perpendicular to $\hat{\mathbf{i}}$. As a matter of fact, if the flight path angle is zero degrees, $\hat{\mathbf{k}}$ points in the same direction as the radius vector. In that case, the y-axis unit vector $\hat{\mathbf{j}}$ completes the unit frame. Since $\hat{\mathbf{j}}$ is perpendicular to the $\hat{\mathbf{i}}\text{-}\hat{\mathbf{k}}$ plane, it is also perpendicular to $\mathbf{V}_{\mathbf{G}_{\mathbf{I}}}$ and $\mathbf{r}_{\mathbf{I}}$. Now because the radius vector is pointing through the centre of the body away from the centre of the inertial frame, the Right-hand-rule (RHR) gives Equation (6.49).

$$\hat{\mathbf{j}} = \frac{\mathbf{r}_{\mathbf{I}} \times \mathbf{V}_{\mathbf{G}_{\mathbf{I}}}}{\|\mathbf{r}_{\mathbf{I}} \times \mathbf{V}_{\mathbf{G}_{\mathbf{I}}}\|} \quad (6.49)$$

Now $\hat{\mathbf{k}}$ can be computed by applying the RHR to $\hat{\mathbf{i}}$ and $\hat{\mathbf{j}}$. This results in Equation (6.50).

$$\hat{\mathbf{k}} = \hat{\mathbf{i}} \times \hat{\mathbf{j}} \quad (6.50)$$

This leaves us with the unit vectors in the body frame defined as a function of the state in the inertial frame.

Figure 6.3: Definition of the body frame unit vectors based on the radius and ground velocity expressed in the inertial frame.

DEFINING THE TRANSFORMATION MATRIX COEFFICIENTS

Now, if the acceleration in the x-direction in the body frame is multiplied with $\hat{\mathbf{i}}$ this a_{x_B} is redefined in the inertial frame by providing a contribution in the x-, y- and z-direction. A similar multiplication can be done for a_{y_B} and $\hat{\mathbf{j}}$, and a_{z_B} and $\hat{\mathbf{k}}$. In matrix form this can be represented by Equation (6.51).

$$[\hat{\mathbf{i}} \quad \hat{\mathbf{j}} \quad \hat{\mathbf{k}}] \cdot \begin{pmatrix} a_{x_B} \\ a_{y_B} \\ a_{z_B} \end{pmatrix} \quad (6.51)$$

Comparing Equation (6.51) to the expression for the transformation matrix provided by Equation (6.46) it can be seen that the coefficients can now be expressed as Equation (6.52).

$$\begin{pmatrix} C_1 \\ C_2 \\ C_3 \end{pmatrix} = \hat{\mathbf{i}} \quad \begin{pmatrix} C_4 \\ C_5 \\ C_6 \end{pmatrix} = \hat{\mathbf{j}} \quad \begin{pmatrix} C_7 \\ C_8 \\ C_9 \end{pmatrix} = \hat{\mathbf{k}} \quad (6.52)$$

Given these definitions, the corresponding auxiliary functions can now be defined.

AUXILIARY FUNCTIONS FOR THE SECOND CASE

With the transformation matrix now defined, Equation (6.9) can be written as Equation (6.53).

$$\begin{pmatrix} a_x \\ a_y \\ a_z \end{pmatrix} = \begin{pmatrix} -\mu_M \frac{x}{r^3} \\ -\mu_M \frac{y}{r^3} \\ -\mu_M \frac{z}{r^3} \end{pmatrix} + [\hat{\mathbf{i}} \quad \hat{\mathbf{j}} \quad \hat{\mathbf{k}}] \cdot \left[\begin{pmatrix} -\frac{D}{m_{MAV}} \\ 0 \\ 0 \end{pmatrix} + \dots \dots \right]_{\mathbf{B}} \mathbb{T}_{\mathbf{z}}(-\psi_T) \mathbb{T}_{\mathbf{y}}(-\epsilon_T) \Big|_{\mathbf{P}} \begin{pmatrix} T \\ m_{MAV} \\ 0 \\ 0 \end{pmatrix} \quad (6.53)$$

In this case, all the auxiliary functions involving the rotation angles and the transformations ($w_{4,5} - w_{4,8}$, $w_{4,13} - w_{4,25}$, $w_{4,40} - w_{4,52}$, $w_{5,2} - w_{5,6}$ and $w_{6,2} - w_{6,7}$) can be discarded and instead new auxiliary functions have to be defined for the new transformation matrix. Please note that the discarded numbers will be reused but now with different function definitions for the second case!

The first auxiliary functions can be found by rewriting Equation (6.48) as a function of the non-discarded auxiliary functions described in Section 6.2.1 and are shown in Equation (6.54).

$$w_{4,13} = C_1 = \frac{V_x + \Omega_M y}{V_G} = \frac{w_{4,9}}{w_{4,12}} \quad w_{4,14} = C_2 = \frac{V_y - \Omega_M x}{V_G} = \frac{w_{4,10}}{w_{4,12}} \quad w_{4,15} = C_3 = \frac{V_z}{V_G} = \frac{x_6}{w_{4,12}} \quad (6.54)$$

In case of the auxiliary functions for $\hat{\mathbf{j}}$ first the cross product has to be computed and the norm of that cross product. This is done in Equation (6.55).

$$\begin{aligned} w_{4,16} &= x_6 x_2 - w_{4,10} x_3 & w_{4,19} &= w_{4,16}^2 + w_{4,17}^2 + w_{4,18}^2 & w_{4,21} &= C_4 = \frac{w_{4,16}}{w_{4,20}} \\ w_{4,17} &= w_{4,9} x_3 - x_6 x_1 & w_{4,20} &= \sqrt{w_{4,19}} & w_{4,22} &= C_5 = \frac{w_{4,17}}{w_{4,20}} \\ w_{4,18} &= w_{4,10} x_1 - w_{4,9} x_2 & & & w_{4,23} &= C_6 = \frac{w_{4,18}}{w_{4,20}} \end{aligned} \quad (6.55)$$

These auxiliary functions can now be used to describe the $\hat{\mathbf{k}}$ functions as shown by Equation (6.56). In this case, the last auxiliary function was named 40 because 26 is already taken up by an auxiliary function for the thrust acceleration.

$$\begin{aligned} w_{4,24} &= C_7 = C_2 C_6 - C_3 C_5 = w_{4,14} w_{4,23} - w_{4,15} w_{4,22} \\ w_{4,25} &= C_8 = C_3 C_4 - C_1 C_6 = w_{4,15} w_{4,21} - w_{4,13} w_{4,23} \\ w_{4,40} &= C_9 = C_1 C_5 - C_2 C_4 = w_{4,13} w_{4,22} - w_{4,14} w_{4,21} \end{aligned} \quad (6.56)$$

Then combining everything results in the expression presented in Equation (6.57) for u_4 , u_5 and u_6 .

$$\begin{aligned} u_4 &= w_{4,39} + w_{4,36} w_{4,13} + w_{4,37} w_{4,21} - w_{4,38} w_{4,24} \\ u_5 &= w_{5,1} + w_{4,36} w_{4,14} + w_{4,37} w_{4,22} - w_{4,38} w_{4,25} \\ u_6 &= w_{6,1} + w_{4,36} w_{4,15} + w_{4,37} w_{4,23} - w_{4,38} w_{4,40} \end{aligned} \quad (6.57)$$

6.2.3. SPHERICAL EQUATIONS

For the Spherical case, the initial conditions are readily provided. The position comes directly from the chosen launch site and the velocity comes from the initial MAV conditions. These are all defined in the rotating frame as depicted in Figure 6.4 and Equation (6.58).

$$\mathbf{R} = \begin{pmatrix} r \\ \delta \\ \tau \end{pmatrix} \quad \mathbf{V} = \begin{pmatrix} V_G \\ \gamma_G \\ \chi_G \end{pmatrix} \quad m_{MAV} \quad (6.58)$$

The different variables are now defined as shown by Equation (6.59) and the derivatives by Equation (6.60). The numbers that were given to the variables are a result of the early derivations.

$$\begin{aligned} x_{16} &= r = h + R_{MOLA} & x_{15} &= V_G \\ x_{12} &= \delta & x_{14} &= \gamma_G & x_7 &= m_{MAV} \\ x_{11} &= \tau & x_{13} &= \chi_G \end{aligned} \quad (6.59)$$

$$\begin{aligned} x'_{16} &= \dot{r} & x'_{15} &= \dot{V}_G \\ x'_{12} &= \dot{\delta} & x'_{14} &= \dot{\gamma}_G & x'_7 &= \dot{m}_{MAV} = -\frac{T}{g_0 I_{sp}} \\ x'_{11} &= \dot{\tau} & x'_{13} &= \dot{\chi}_G \end{aligned} \quad (6.60)$$

The derivatives given in Equation (6.60) are already provided by Mooij (1994) in the rotating frame and include the rotational effects. A simplified form can be seen in Equations (6.61) and (6.62). This is why it

Figure 6.4: Definition of the Spherical coordinates (Mooij, 1994).

was decided to perform the TSI for the Spherical case in the rotating frame. At the end of the integration the variables can then be transformed to the inertial frame for comparison.

$$x'_{16} = \dot{r} = V_G s \gamma_G \quad x'_{12} = \dot{\delta} = \frac{V_G c \chi_G c \gamma_G}{r} \quad x'_{11} = \dot{\tau} = \frac{V_G s \chi_G c \gamma_G}{r c \delta} \quad (6.61)$$

$$\begin{aligned} x'_{15} = \dot{V}_G &= \Omega_M^2 r c \delta (s \gamma_G c \delta - c \gamma_G s \delta c \chi_G) + \frac{T c \psi_T c \epsilon_T}{m} - \frac{D}{m} - \frac{\mu_M}{r^2} s \gamma_G \\ x'_{14} = \dot{\gamma}_G &= 2 \Omega_M c \delta s \chi_G + \frac{V_G}{r} c \gamma_G + \frac{\Omega_M^2 r c \delta}{V_G} (c \delta c \gamma_G + s \gamma_G s \delta c \chi_G) + \frac{T s \epsilon_T}{V_G m} - \frac{\mu_M}{V_G r^2} c \gamma_G \\ x'_{13} = \dot{\chi}_G &= 2 \Omega_M \left(s \delta - \frac{c \delta s \gamma_G c \chi_G}{c \gamma_G} \right) + \frac{V_G}{r} c \gamma_G \frac{s \delta}{c \delta} s \chi_G + \frac{\Omega_M^2 r c \delta s \delta s \chi_G}{V_G c \gamma_G} + \frac{T s \psi_T c \epsilon_T}{V_G m c \gamma_G} \end{aligned} \quad (6.62)$$

The last term in the first two expressions of Equation (6.62) correspond to the acceleration contribution of the gravity. The first expression has a drag component and all three have a thrust component similar to the Cartesian cases. The rest of the terms come from the rotational effects. In this case it was decided to define the drag as an auxiliary equation x_{27} , which will be discussed in more detail later in this section.

AUXILIARY FUNCTIONS FOR THE SPHERICAL CASE

Before the auxiliary functions for Equations (6.61) and (6.61) can be written, some standard auxiliary functions have to be defined first. These include δ , γ_G and χ_G . The numbering is based on early derivations and do not correspond to the definitions provided for the Cartesian cases! The angle auxiliary functions are defined in Equation (6.63).

$$\begin{aligned}
w_{4,4} &= s\delta = sx_{12} & w_{4,7} &= s\gamma_G = sx_{14} \\
w_{4,5} &= c\chi_G = cx_{13} & w_{4,8} &= c\gamma_G = cx_{14} \\
w_{4,6} &= c\delta = cx_{12} & w_{4,9} &= s\chi_G = sx_{13}
\end{aligned} \tag{6.63}$$

Some expression for the thrust are also required. These are similar to the equations defined in Section 6.2.1 but are repeated in Equation (6.64) for convenience.

$$\begin{aligned}
w_{4,26} &= \cos\psi_T & w_{4,28} &= \sin\psi_T & w_{4,32} &= \frac{1}{x_7} \\
w_{4,27} &= \cos\epsilon_T & w_{4,29} &= \sin\epsilon_T
\end{aligned} \tag{6.64}$$

Now the auxiliary functions can be written for $x'_{11} = u_{11}$ till $x'_{16} = u_{16}$ and are shown in Equations (6.65) to (6.70) respectively.

$$\begin{aligned}
w_{11,0} &= V_G c\gamma_G = x_{15} w_{4,8} & w_{11,2} &= w_{11,1} s\chi_G = w_{11,1} w_{4,9} \\
w_{11,1} &= \frac{w_{11,0}}{r} = \frac{w_{11,0}}{x_{16}} & w_{11,3} &= \frac{w_{11,2}}{c\delta} = \frac{w_{11,2}}{w_{4,6}} & u_{11} &= w_{11,3}
\end{aligned} \tag{6.65}$$

$$w_{12,1} = w_{11,1} c\chi_G = w_{11,1} w_{4,5} \quad u_{12} = w_{12,1} \tag{6.66}$$

$$\begin{aligned}
w_{13,0} &= s\psi_T c\epsilon_T = w_{4,28} w_{4,27} & w_{13,5} &= w_{13,3} s\chi_G + w_{13,4} = w_{13,3} w_{4,9} + w_{13,4} \\
w_{13,1} &= s\gamma_G c\chi_G = w_{4,7} w_{4,5} & w_{13,6} &= \frac{w_{13,5}}{V_G} = \frac{w_{13,5}}{x_{15}} \\
w_{13,2} &= \Omega_M^2 r c\delta = \Omega_M^2 x_{16} w_{4,6} & w_{13,7} &= -2\Omega_M c\delta w_{13,1} + w_{13,6} = -2\Omega_M w_{4,6} w_{13,1} + w_{13,6} & u_{13} &= w_{13,9} \\
w_{13,3} &= w_{13,2} s\delta = w_{13,2} w_{4,4} & w_{13,8} &= \frac{w_{13,7}}{c\gamma_G} = \frac{w_{13,7}}{w_{4,8}} \\
w_{13,4} &= \frac{T w_{13,0}}{x_7} = T w_{13,0} w_{4,32} & w_{13,9} &= (2\Omega_M + w_{11,3}) s\delta + w_{13,8} = (2\Omega_M + w_{11,3}) w_{4,4} + w_{13,8}
\end{aligned} \tag{6.67}$$

$$\begin{aligned}
w_{14,0} &= \frac{T s\epsilon_T}{x_7} = T w_{4,29} w_{4,32} & w_{14,5} &= w_{14,4} + w_{13,2} w_{14,1} + w_{14,0} \\
w_{14,1} &= c\delta c\gamma_G + w_{13,1} s\delta = w_{4,6} w_{4,8} + w_{13,1} w_{4,4} & w_{14,6} &= \frac{w_{14,5}}{V_G} = \frac{w_{14,5}}{x_{15}} \\
w_{14,2} &= -\mu_M c\gamma_G = -\mu_M w_{4,8} & w_{14,7} &= 2\Omega_M c\delta s\chi_G + w_{11,1} + w_{14,6} = 2\Omega_M w_{4,6} w_{4,9} + w_{11,1} + w_{14,6} \\
w_{14,3} &= r^2 = x_{16}^2 & u_{14} &= w_{14,7} \\
w_{14,4} &= \frac{w_{14,2}}{w_{14,3}}
\end{aligned} \tag{6.68}$$

$$\begin{aligned}
w_{15,0} &= T c\psi_T c\epsilon_T - D = T w_{4,26} w_{4,27} - x_{27} & w_{15,4} &= c\gamma_G c\chi_G = w_{4,8} w_{4,5} \\
w_{15,1} &= \frac{w_{15,0}}{m} = \frac{w_{15,0}}{x_7} & w_{15,5} &= s\gamma_G c\delta - w_{15,4} s\delta = w_{4,7} w_{4,6} - w_{15,4} w_{4,4} \\
w_{15,2} &= -\mu_M s\gamma_G = -\mu_M w_{4,7} & w_{15,6} &= w_{13,2} w_{15,5} + w_{15,1} + w_{15,3} \\
w_{15,3} &= \frac{w_{15,2}}{w_{14,3}} & u_{15} &= w_{15,6}
\end{aligned} \tag{6.69}$$

$$w_{16,1} = V_G s\gamma_G = x_{15} w_{4,7} \quad u_{16} = w_{16,1} \tag{6.70}$$

DRAG ACCELERATION AS AUXILIARY VARIABLE

The drag acceleration for the Spherical case is similar to the Cartesian case, except this time it was chosen to use auxiliary variables to describe the drag. This means that auxiliary equations have to be defined as is shown in Equation (6.71). Also, this means that auxiliary derivatives are required for each of these equations. Equation (6.72) shows the different derivatives corresponding to the equations.

$$\begin{aligned}
 x_{27} &= D = \frac{1}{2} \rho V_G^2 S C_D = \frac{1}{2} S x_{28} x_{15}^2 x_{29} \\
 x_{28} &= \rho = e^{x_{30}} \\
 x_{29} &= C_D \\
 x_{30} &= P_{\rho 10} x_{31}^{10} + P_{\rho 9} x_{31}^9 + P_{\rho 8} x_{31}^8 + P_{\rho 7} x_{31}^7 + P_{\rho 6} x_{31}^6 + P_{\rho 5} x_{31}^5 + P_{\rho 4} x_{31}^4 + P_{\rho 3} x_{31}^3 + P_{\rho 2} x_{31}^2 + P_{\rho 1} x_{31} + P_{\rho 0} \\
 x_{31} &= h = r - R_{MOLA} = x_{16} - R_{MOLA}
 \end{aligned} \tag{6.71}$$

$$\begin{aligned}
 x'_{27} &= \frac{1}{2} S x_{15} (x_{15} (x_{29} x'_{28} + x_{28} x'_{29}) + 2 x_{28} x_{29} x'_{15}) \\
 x'_{28} &= x'_{30} x_{28} \\
 x'_{30} &= x'_{31} (10 P_{\rho 10} x_{31}^9 + 9 P_{\rho 9} x_{31}^8 + 8 P_{\rho 8} x_{31}^7 + 7 P_{\rho 7} x_{31}^6 + 6 P_{\rho 6} x_{31}^5 + \dots \\
 &\quad \dots + 5 P_{\rho 5} x_{31}^4 + 4 P_{\rho 4} x_{31}^3 + 3 P_{\rho 3} x_{31}^2 + 2 P_{\rho 2} x_{31} + P_{\rho 1}) \\
 x'_{31} &= x'_{16}
 \end{aligned} \tag{6.72}$$

The auxiliary derivatives described in Equation (6.72) can now be used to define the auxiliary functions. These are described in Equations (6.73) to (6.75) for u_{27} , u_{28} and u_{30} respectively. In this case $u_{31} = u_{16}$.

$$\begin{aligned}
 w_{27,1} &= C_D \dot{\rho} = x_{29} u_{28} & w_{27,4} &= V_G (w_{27,1} + w_{27,2}) = x_{15} (w_{27,1} + w_{27,2}) \\
 w_{27,2} &= \rho \dot{C}_D = x_{28} u_{29} & w_{27,5} &= w_{27,3} \dot{V}_G = w_{27,3} u_{15} & u_{27} &= \frac{1}{2} S w_{27,6} \\
 w_{27,3} &= \rho C_D = x_{28} x_{29} & w_{27,6} &= V_G (w_{27,4} + w_{27,5}) = x_{15} (w_{27,4} + w_{27,5})
 \end{aligned} \tag{6.73}$$

$$\begin{aligned}
 w_{28,1} &= u_{30} \rho = u_{30} x_{28} & u_{28} &= w_{28,1}
 \end{aligned} \tag{6.74}$$

$$\begin{aligned}
 w_{30,1} &= h^9 = x_{31}^9 & w_{30,6} &= h^4 = x_{31}^4 \\
 w_{30,2} &= h^8 = x_{31}^8 & w_{30,7} &= h^3 = x_{31}^3 \\
 w_{30,3} &= h^7 = x_{31}^7 & w_{30,8} &= h^2 = x_{31}^2 \\
 w_{30,4} &= h^6 = x_{31}^6 & w_{30,9} &= u_{31} (10 P_{\rho 10} w_{30,1} + \dots + 3 P_{\rho 3} w_{30,8} + 2 P_{\rho 2} x_{31} + P_{\rho 1}) \\
 w_{30,5} &= h^5 = x_{31}^5 & u_{30} &= w_{30,9}
 \end{aligned} \tag{6.75}$$

Again, three additional auxiliary equations are required for the $C_D - M$ relation (see Figure 3.8) and are presented in Equation (6.76).

$$\begin{aligned}
 x_{32} &= M = \frac{V_G}{a} = \frac{x_{15}}{x_{33}} \\
 x_{33} &= a = \sqrt{\gamma_a R_a^* T_a} = \sqrt{\gamma_a R_a^* x_{34}} \quad \text{where} \quad R_a^* = \frac{R_a}{M_a} \\
 x_{34} &= T_a
 \end{aligned} \tag{6.76}$$

In this case the conditional relations shown in Equation (6.77) are not used directly in the recurrence relations, but only serve as initial conditions. Again, the $P_{C_D \text{ number, section}}$ are the polynomial fit coefficients as provided in Table 3.5.

$$x_{29} = C_D = \begin{cases} x_{29,1} = 0.2, & \text{for } 0 \leq x_{32} < 0.5 \\ x_{29,2} = P_{C_D,1,2}x_{32} + P_{C_D,0,2}, & \text{for } 0.5 \leq x_{32} < 1 \\ x_{29,3} = P_{C_D,1,3}x_{32} + P_{C_D,0,3}, & \text{for } 1 \leq x_{32} < 1.3 \\ x_{29,4} = P_{C_D,1,4}x_{32} + P_{C_D,0,4}, & \text{for } 1.3 \leq x_{32} < 2.5 \\ x_{29,5} = P_{C_D,1,5}x_{32} + P_{C_D,0,5}, & \text{for } 2.5 \leq x_{32} < 4 \\ x_{29,6} = 0.3, & \text{for } x_{32} \geq 4 \end{cases} \quad (6.77)$$

The corresponding derivatives that will have to be used for the recurrence relations are presented in Equation (6.78).

$$x'_{29} = \begin{cases} x'_{29,1} = 0, & \text{for } 0 \leq x_{32} < 0.5 \\ x'_{29,2} = P_{C_D,1,2}x'_{32}, & \text{for } 0.5 \leq x_{32} < 1 \\ x'_{29,3} = P_{C_D,1,3}x'_{32}, & \text{for } 1 \leq x_{32} < 1.3 \\ x'_{29,4} = P_{C_D,1,4}x'_{32}, & \text{for } 1.3 \leq x_{32} < 2.5 \\ x'_{29,5} = P_{C_D,1,5}x'_{32}, & \text{for } 2.5 \leq x_{32} < 4 \\ x'_{29,6} = 0, & \text{for } x_{32} \geq 4 \end{cases} \quad (6.78)$$

The Mach derivative and corresponding speed of sound derivative are then described in Equation (6.79).

$$\begin{aligned} x'_{32} &= \frac{x_{33}x'_{15} - x_{15}x'_{33}}{x_{33}^2} \\ x'_{33} &= \frac{\gamma_a R_a^*}{2x_{33}} x'_{34} \end{aligned} \quad (6.79)$$

For the drag coefficient, there are no auxiliary functions required. That is why x' in Equation (6.78) can simply be replaced by u . The Mach number and the speed of sound do require auxiliary functions and are described in Equations (6.80) and (6.81) respectively.

$$\begin{aligned} w_{32,1} &= a\dot{V}_G = x_{33}u_{15} & w_{32,3} &= a^2 = x_{33}^2 \\ w_{32,2} &= V_G\dot{a} = x_{15}u_{33} & w_{32,4} &= \frac{w_{32,1} - w_{32,2}}{w_{32,3}} & u_{32} &= w_{32,4} \end{aligned} \quad (6.80)$$

$$w_{33,1} = \frac{\dot{T}_a}{a} = \frac{u_{34}}{x_{33}} \quad u_{33} = w_{33,1} \quad (6.81)$$

The last relations that still need to be described are the ones for the temperature T_a . Similar to C_D the corresponding auxiliary equations, shown by Equation (6.82) are only used for the initial conditions. Again, $P_{Tnumber,section}$ are the polynomial fit coefficients as provided in Table 3.2.

$$x_{34} = T_a = \begin{cases} x_{34,1} = P_{T1,1}x_{31} + P_{T0,1}, & \text{for } -0.6 \leq x_{31} < 5.04 \\ x_{34,2} = P_{T3,2}x_{31}^3 + P_{T2,2}x_{31}^2 + P_{T1,2}x_{31} + P_{T0,2}, & \text{for } 5.04 \leq x_{31} < 35.53 \\ x_{34,3} = P_{T6,3}x_{31}^6 + P_{T5,3}x_{31}^5 + P_{T4,3}x_{31}^4 + P_{T3,3}x_{31}^3 + \dots \\ \quad \dots + P_{T2,3}x_{31}^2 + P_{T1,3}x_{31} + P_{T0,3}, & \text{for } 35.53 \leq x_{31} < 75.07 \\ x_{34,4} = P_{T8,4}x_{31}^8 + P_{T7,4}x_{31}^7 + P_{T6,4}x_{31}^6 + P_{T5,4}x_{31}^5 \\ \quad + P_{T4,4}x_{31}^4 + P_{T3,4}x_{31}^3 + P_{T2,4}x_{31}^2 + P_{T1,4}x_{31} + P_{T0,4}, & \text{for } 75.07 \leq x_{31} < 170.05 \\ x_{34,5} = 136.5, & \text{for } x_{31} \geq 170.05 \end{cases} \quad (6.82)$$

The corresponding derivatives that are used for the recurrence relations are presented in Equation (6.83).

$$x'_{34} = \begin{cases} x'_{34,1} = P_{T1,1} x'_{31}, & \text{for } -0.6 \leq x_{31} < 5.04 \\ x'_{34,2} = (3P_{T3,2} x_{31}^2 + 2P_{T2,2} x_{31} + P_{T1,2}) x'_{31}, & \text{for } 5.04 \leq x_{31} < 35.53 \\ x'_{34,3} = (6P_{T6,3} x_{31}^5 + 5P_{T5,3} x_{31}^4 + 4P_{T4,3} x_{31}^3 + \dots \\ \quad \dots + 3P_{T3,3} x_{31}^2 + 2P_{T2,3} x_{31} + P_{T1,3}) x'_{31}, & \text{for } 35.53 \leq x_{31} < 75.07 \\ x'_{34,4} = (8P_{T8,4} x_{31}^7 + 7P_{T7,4} x_{31}^6 + 6P_{T6,4} x_{31}^5 + 5P_{T5,4} x_{31}^4 + \dots \\ \quad \dots + 4P_{T4,4} x_{31}^3 + 3P_{T3,4} x_{31}^2 + 2P_{T2,4} x_{31} + P_{T1,4}) x'_{31}, & \text{for } 75.07 \leq x_{31} < 170.05 \\ x'_{34,5} = 0, & \text{for } x_{31} \geq 170.05 \end{cases} \quad (6.83)$$

All the power relations in Equation (6.83) were already described in auxiliary functions in Equation (6.75). Therefore, depending on the section, the equations presented in Equation (6.83) can be rewritten by simply replacing x' by u and the auxiliary functions. This is shown in Equation (6.84).

$$u_{34} = \begin{cases} u_{34,1} = P_{T1,1} u_{31}, & \text{for } -0.6 \leq x_{31} < 5.04 \\ u_{34,2} = (3P_{T3,2} w_{30,2} + 2P_{T2,2} x_{31}) u_{31} + P_{T1,2} u_{31}, & \text{for } 5.04 \leq x_{31} < 35.53 \\ u_{34,3} = (6P_{T6,3} w_{30,5} + 5P_{T5,3} w_{30,4} + 4P_{T4,3} w_{30,3} + \dots \\ \quad \dots + 3P_{T3,3} w_{30,2} + 2P_{T2,3} x_{31}) u_{31} + P_{T1,3} u_{31}, & \text{for } 35.53 \leq x_{31} < 75.07 \\ u_{34,4} = (8P_{T8,4} w_{30,7} + 7P_{T7,4} w_{30,6} + 6P_{T6,4} w_{30,5} + 5P_{T5,4} w_{30,4} + \dots \\ \quad \dots + 4P_{T4,4} w_{30,3} + 3P_{T3,4} w_{30,2} + 2P_{T2,4} x_{31}) u_{31} + P_{T1,4} u_{31}, & \text{for } 75.07 \leq x_{31} < 170.05 \\ u_{34,5} = 0, & \text{for } x_{31} \geq 170.05 \end{cases} \quad (6.84)$$

Now all the information that is required to compute the recurrence relation for the drag is available. Please note that there is a certain order in which these equations have to be computed, since they depend on each other. Table 6.1 shows this order.

Table 6.1: Order of auxiliary equations and derivatives computations

Auxiliary equations				Auxiliary derivatives			
Order	x_n	Order	x_n	Order	u_n	Order	u_n
0	$x_7, x_{11}, x_{12}, x_{13}, x_{14}, x_{15}, x_{16}$	4	x_{32}	7	$u_7, u_{11}, u_{12}, u_{16}$	11	u_{32}
1	x_{31}	5	x_{29}	8	u_{31}	12	u_{29}
2	x_{30}, x_{34}	6	x_{27}	9	u_{30}, u_{34}	13	u_{27}
3	x_{33}, x_{28}			10	u_{28}, u_{33}	14	u_{13}, u_{14}, u_{15}

6.2.4. RECURRENCE RELATIONS

Now that all the auxiliary functions are known, they can be used to determine the required recurrence relations. In order to write these concisely and following the same convention as used by Scott and Martini (2008), a number of extra parameters will have to be introduced. The Taylor series coefficients can be written as described by Equation (6.85). Where n is the variable number and k is the order of the derivative.

$$\frac{x_n^{(k)}}{k!} \triangleq X_n(k) \quad \text{where } k \geq 1 \quad (6.85)$$

A similar expression is defined for u_n and w_n as well as the place-holder functions f_n and g_n which are all shown in Equation (6.86).

$$U_n(k) \triangleq \frac{u_n^{(k)}}{k!} \quad W_n(k) \triangleq \frac{w_n^{(k)}}{k!} \quad F_n(k) \triangleq \frac{f_n^{(k)}}{k!} \quad G_n(k) \triangleq \frac{g_n^{(k)}}{k!} \quad (6.86)$$

Then remembering that $u_n = x'_n$ and using Equation (6.85) a relation can be described between X_n and U_n as shown in Equation (6.87) (Scott and Martini, 2008).

$$\begin{aligned}
u_n^{(k-1)} = x_n^{(k)} &\Rightarrow \frac{u_n^{(k-1)}}{(k-1)!} = \frac{x_n^{(k)}}{(k-1)!} \Rightarrow \\
U_n(k-1) = kX_n(k) &\Rightarrow X_n(k) = \frac{U_n(k-1)}{k}
\end{aligned} \tag{6.87}$$

Using these definitions, the auxiliary functions can be written into reduced auxiliary functions $W(k)$ for the three cases. The equations stay the same, but the lower-case letters are replaced by their upper-case counterparts. A complete list of the reduced auxiliary functions (starting at $k = 2$, or the second derivative u') for the three cases is presented in Appendix D. As was mentioned before, all the auxiliary functions have been defined such that they incorporate one of the following operations: multiplication, division, power, exponential or trigonometric. This has been done because recurrence relations exist for these simple operations as provided by [Jorba and Zou \(2005\)](#). These recurrence relations are written using the definitions from Equation (6.86) and are described in Equations (6.88) to (6.94).

$$\text{for } f_n \pm g_n \Rightarrow W_{n,\pm}(k) = F_n(k) \pm G_n(k) \tag{6.88}$$

$$\text{for } f_n g_n \Rightarrow W_{n,mult}(k) = \sum_{j=0}^k F_n(j) G_n(k-j) \tag{6.89}$$

$$\text{for } \frac{f_n}{g_n} \Rightarrow W_{n,div}(k) = \frac{1}{G_n(0)} \left[F_n(k) - \sum_{j=1}^k G_n(j) W_{n,div}(k-j) \right] \tag{6.90}$$

$$\text{for } f_n^\alpha \Rightarrow W_{n,pow}(k) = \frac{1}{kF_n(0)} \sum_{j=0}^{k-1} [k\alpha - j(\alpha+1)] F_n(k-j) W_{n,pow}(j) \tag{6.91}$$

$$\text{for } e^{f_n} \Rightarrow W_{n,exp}(k) = \frac{1}{k} \sum_{j=0}^{k-1} (k-j) W_{n,exp}(j) F_n(k-j) \tag{6.92}$$

$$\text{for } \cos f_n \Rightarrow W_{n,cos}(k) = -\frac{1}{k} \sum_{j=1}^k j W_{n,sin}(k-j) F_n(j) \tag{6.93}$$

$$\text{for } \sin f_n \Rightarrow W_{n,sin}(k) = \frac{1}{k} \sum_{j=1}^k j W_{n,cos}(k-j) F_n(j) \tag{6.94}$$

Checking the presented equations it can be seen that Equations (6.93) and (6.94) are interdependent. This means that whenever a cosine recurrence relation has to be computed, the same recurrence relation for sine (with at least order $k-1$) has to be computed at the same time (and vice versa). All these equations have been derived by [Jorba and Zou \(2005\)](#) using the general Leibniz rule for the k^{th} derivative of a multiplication as portrayed in Equation (6.95).

$$(f_n g_n)^{(k)} = \sum_{j=0}^k \binom{k}{j} f_n^{(j)} g_n^{(k-j)} \tag{6.95}$$

Combining Equation (6.95) and the definition of the reduced derivative for the auxiliary function (see Equation (6.86)) results in Equation (6.96). This equation, when rewritten to include the reduced derivatives for f_n and g_n , results in Equation (6.89).

$$W_{n,mult}(k) = \frac{1}{k!} \sum_{j=0}^k \binom{k}{j} f_n^{(j)} g_n^{(k-j)} \tag{6.96}$$

With all the recurrence relations now known, and using the definition of Equation (6.87) the updated state can be described using the Taylor series expansion as described in Equation (6.97).

$$x_n(t+h) = \sum_{k=0}^K \frac{x_n^{(k)}(t)}{k!} h^k + T_{n,K} = \sum_{k=0}^K X_n(k) h^k + T_{n,K} \quad \text{with } n = 1, \dots, 7 \tag{6.97}$$

Here K is the order of the series to which it has to be evaluated and $T_{n,K}$ is the truncation error. Please note that all the Taylor series coefficients computed for the auxiliary equations are only needed to determine the Taylor series coefficients of the state variables (which is why they are auxiliary).

7

PROGRAM OPTIMISATION TOOL

To perform the analysis associated with this thesis, a simulation and optimisation program is used. This optimisation tool is comprised of both existing (Section 7.1) and newly developed software (Section 7.2). It is written in C++ and is based on the [Tudat](#) structure. The purpose of the software is to simulate the trajectory of the [MAV](#) and optimise this trajectory with respect to the lowest propellant mass required. This tool is written such that the performance of Runge-Kutta-Fehlberg 4th (5th) order ([RKF45](#)) and [TSI](#) can be compared.

7.1. EXISTING SOFTWARE

The use of existing software can greatly improve the performance of the final tool and save time as well. Another important reason to use existing software is that this will make it easier for other people to use and incorporate into their software as well. The existing software used for this thesis is software that is currently being used by the space department of the TU Delft and (in case of [SNOPT](#) and Mars-[GRAM](#)) by the mission design section at [JPL](#).

7.1.1. TUDAT

[Tudat](#) is, as the name suggests, a toolbox that can be used to solve numerous astrodynamic problems ([Dirkx et al., 2016](#)). It was and still is being developed by students and staff of the Delft University of Technology. Specifically by the section Astrodynamics and Space missions of the Aerospace Engineering faculty. It is programmed in C++ and consists of a number of libraries. These libraries can be called upon by the user to invoke different [Tudat](#) functionalities such as standard reference frame transformations or often used integrators. The available software is completely validated and comes with its own tests to make sure that everything is working properly. It itself uses two external libraries: Eigen and Boost. Both these libraries will be discussed in Sections 7.1.2 and 7.1.3 respectively. Figure 7.1 shows [Tudat](#) with the different libraries that are used within the [Tudat](#) Bundle including the core functions ([Tudat Core](#)). In this thesis, the [Tudat](#) libraries are used for all standard mathematical and astrodynamic operations.

Figure 7.1: [Tudat](#) structure

7.1.2. EIGEN

Eigen is an external C++ library that was written to perform linear algebra computations¹. The software is free and easy to use, which is why it is widely used by the C++ community and thus also within *Tudat* (Dirkx et al., 2016). Another advantage is that because it does not use any source files, it does not need to be build before using it. The Eigen libraries contain a number of standardized matrices and vectors, each with its own characteristics. An example of an often used vector is *Vector3d* (or *Eigen::Vector3d*), which can for instance be used to store the Cartesian position of a satellite. Here the 3 shows that it can store 3 values/parameters and the *d* shows that these are of the type *double*. It is mentioned on the *Tudat* wiki (Dirkx et al., 2016) that these Eigen vectors and matrices should only be used if required for linear algebra computations. For ordinary storage, the C++ arrays, vectors and matrices should be used to save both storage and computation time.

7.1.3. BOOST

Boost is a slightly more complicated set of C++ libraries, where compared to the Eigen library, Boost first has to be compiled before being able to use all of its functionalities. Fortunately, this compiling is performed by *Tudat* automatically when setting it up for the first time. Boost is described as an addition to the standard C++ libraries, thus adding more functionalities (Dirkx et al., 2016)². Within *Tudat*, Boost is used to pass free and class functions as an argument to another object and also for dynamic allocation using so-called pointers. Four libraries that are often used within *Tudat* are *boost::function*, *boost::bind*, *boost::shared_ptr* and *boost::make_shared*. The first two libraries are used to pass functions (a function is pointed to by *function* and called by *bind*) and the last two are used in case of dynamic allocation (*shared_ptr* is the pointer and *make_shared* is the object creator that returns a shared pointer to the created object).

7.1.4. PAGMO

PaGMO is a free optimisation tool developed by European Space Agency (ESA)s Advanced Concepts Team (ACT). It uses parallel computations to perform the optimisation and can even optimise for multi-objective problems. Parallel computation is the act of performing multiple computations on the same machine using different CPU cores. This allows the cost function to be computed for different sets of optimisation parameters at the same time and thus reducing the total CPU time required. However, this only works if the cost function evaluations are independent, which is not always the case (e.g. Dynamic Differential Evolution (DE) described by Qing (2009)). The tool itself incorporates many different local and global optimisation methods as mentioned by Izzo (2012), among which the optimisation method used in this thesis Monotonic Basin Hopping (MBH). This method has been written in *PaGMO* in such a way that it can use any of the provided local optimisers. *PaGMO* is written in C++ and requires the shared libraries of Boost to run³. Interfaces to external libraries are also provided, which can incorporate for instance *SNOPT* as a local optimisation method. In this thesis *SNOPT* is used as the local optimiser for MBH as implemented by *PaGMO*. More information on *SNOPT* is provided in Section 7.1.5. For *SNOPT* to be recognised by *PaGMO*, it has to be installed separately. Figure 7.2 shows *PaGMO* with the internally used Boost library and the externally called *SNOPT* software.

Figure 7.2: *PaGMO* structure

7.1.5. SNOPT

SNOPT was introduced by Gill *et al.* (2002) as a Sequential Quadratic Programming (**SQP**) method. It uses the first function derivatives and is very effective with highly constrained problems such as trajectory optimisation. Because it is based on **SQP** it is only able to find the local optimum and it is thus not guaranteed that this is also the global optimum. By combining **SNOPT** and **MBH** the global optimum can indeed be found or approached. The tool itself does not require that many evaluations, which is why it is very useful for complex problems with many optimisation variables (Gill *et al.*, 2008). The code for **SNOPT** has been written in Fortran, but can easily be translated to C,C++ using *f2c* which is provided with **SNOPT** as well ⁴. This way it can be called by **PaGMO**. It should be noted that **SNOPT** is not free and can only be used under a licence agreement.

7.1.6. MARS-GRAM

Mars-GRAM is a high-fidelity atmospheric model developed by NASA to simulate the global atmospheric conditions on Mars (Justh and Justus, 2008) ⁵. The model is based on NASA Ames Mars General Circulation Model (for altitudes between 0-80 km) and Mars Thermospheric General Circulation model (for altitude above 80 km). It can provide density, temperature and pressure data (among other data) with respect to the current altitude, latitude and longitude on Mars. Seasonal variations are taken into account in the model as well, which is why different calendar dates will result in different atmospheric compositions. The tool can be used within a simulation tool or as a separate executable. Unfortunately, because it is so detailed, each computation requires a lot of CPU time. This is why it was decided to use the stand-alone Mars-GRAM executable to generate a detailed table with atmospheric data as a function of altitude, latitude and longitude at the start of the optimisation. Even generating this table required a lot of CPU time (on average a single computation using the stand-alone executable took 67.9 seconds to complete). The starting altitude was set at -0.6 km **MOLA** and advanced with a step-size of 0.1 km to 320 km altitude to cover the entire range that the **MAV** would have to cover. Also, the latitude and longitude were varied within 10 degrees from the launch site with a step-size of 1 degree. A Matlab script was written to extract the relevant atmospheric data from the Mars-GRAM output files and write them into a .csv file, thus creating the required atmospheric data table. The atmospheric data in this table was then interpolated to provide an estimate of the atmospheric characteristics at every point along the ascent trajectory, which is required to compute the drag at each time step. Some of the earlier versions of Mars-GRAM are available for free (such as the Mars-GRAM 2005 version used in this thesis), however, the latests versions (such as the Mars-GRAM 2010 version used as a back-up in this thesis) require a licence agreement.

7.2. DEVELOPED SOFTWARE

This section of the software chapter describes the software that either had to be developed around existing software/libraries or had to be developed from scratch (the **TSI** propagator). Each piece of software is accompanied by the corresponding software architecture. Every next piece of software then indirectly incorporates the previous architecture through the use of the completed tool.

7.2.1. RK4 AND RKF PROPAGATOR

The **RK4** and **RKF** (or traditional) propagator architecture is described in Figure 7.3. It starts with the current state, which is then passed on to the state derivative function. The state derivative function is used by the **RK4** and **RKF** integrators to determine the next state by calling the function a number of times depending on the used method. Both **RK4** and **RKF45** (and higher order **RKF** integrators) are already available through the **Tudat** libraries. **RK4** can be called by including the `rungeKutta4Integrator.h` header file, and **RKF45** can be called by including the `rungeKuttaVariableStepSizeIntegrator.h` header file. This integration process is repeated until the final condition is met. Within the state derivative function all the state derivatives are updated and stored. The current position is used to update the gravitational acceleration on the **MAV**, the current mass is used to determine the accelerations caused by the thrust and finally the complete state is required to determine the accelerations caused by the drag. Both the drag and thrust accelerations have to be transformed to the inertial frame using the updated angles from the current state. The function also computes the current mass flow rate, however since the thrust is constant, this does not change over time. In the state derivative function, all the

⁴More documentation on **SNOPT** can be found on http://www.sbsi-sol-optimize.com/asp/sol_products_snopt_desc.htm [Accessed 9 March 2016]

⁵NASA website: <http://see.msfc.nasa.gov/model-Marsgram> [Accessed 9 March 2016]

transformations are governed by pre-developed functions within the [Tudat](#) library, which includes the state transformations and the frame transformation from the body frame to the inertial frame. The transformation from the propulsion frame to the body frame is however not included in [Tudat](#) and had to be written.

All blocks represent a different action. These actions might be performed in classes, header files and/or source files. More information on the classification of the different blocks can be found in [Appendix C](#).

7.2.2. TSI PROPAGATOR

The [TSI](#) propagator has a significantly different architecture compared to the traditional propagator as can be seen in [Figure 7.4](#). [TSI](#) requires an initial order and step-size to start the integration process. In this thesis it has been decided to keep the order the same throughout the entire integration. The step-size will change during the integration depending on the Taylor series evaluations. The initial state is set as the current state and is fed into the [TSI](#) block. Within this block, first the auxiliary equations and functions are called, which were set-up for this particular problem. They are evaluated using the current state. These auxiliary equations and functions already include all the reference frame and coordinate transformations, as well as approximate atmospheric parameter functions. This is required to set-up the recurrence relations, which is where [TSI](#) differs from the traditional propagator. Once the auxiliary equations and functions have been computed they are used to compute the Taylor coefficients through the recurrence relations set-up for the thesis problem. These coefficients are then stored for later use and are also passed to the block creating the Taylor series expansion for every state variable thus creating the updated state. The last two coefficients are then used to determine the next step-size. This continues until the final integration condition has been met.

7.2.3. OPTIMISER

The optimisation software is a combination of the [SNOPT](#) local optimisation tool and [PaGMO's MBH](#). Even though both these tools were already available and did not have to be developed, it is still important to understand how the rest of the software interacts with the optimiser. This is why [Figure 7.5](#) shows the architecture of the [MBH](#) optimiser. It starts with the initial generation of the optimisation parameters, after which the 'Number of not improved iterations' is set to zero. This is then fed into the local optimiser, where the trajectory is integrated using the previously described tools. Once a local optimised trajectory is found, it is stored if it is better than the previous local optimised trajectory and the counter is set to zero again. If the newly found trajectory is not better than the current best the 'Number of not improved iterations' is increased by one. Once the maximum number of not improved iterations is met, the current best optimal trajectory (which is the optimum for the current "funnel") is stored and the process is repeated till the final global optimisation condition is met. At this point the global optimum is the best optimal trajectory from all the funnels computed at that time, which is then returned as the program solution.

VERIFICATION AND VALIDATION

Verification is the process of determining whether a program meets the requirements or not. Is it working the way it is suppose to? As soon as it works and produces output (verified), these outputs can be compared to other data from which it is known that it is correct. This is called validation. If a program is verified and validated, the outputs should be correct. Fortunately, all the existing software has already been validated, which means that they only still have to be verified to make sure everything is working properly on the simulation computer. Each of the software packages comes with tests which can be used to do this. If all the tests are passed it means that the software is verified for the computer and ready to use. Since [Tudat](#) shipped with Eigen and Boost, the [Tudat](#) test files also test these libraries. All the test were passed, which means that the [Tudat](#), Eigen and Boost libraries are working properly. However, because the integrators are an intricate part of this thesis, it was decided to perform a separate verification for the Runge-Kutta integrators. This verification is described in Section 8.2. Similarly, [PaGMO](#) was verified using its test files.

SNOPT verification still has to be done and added!! As soon as I can get it to work....

Mars-GRAM also came with its own verification test, where three delivered output files had to be replicated. These verification tests were also successful.

8.1. INTERPOLATION

8.2. RK4 AND RKF INTEGRATORS

The tutorial page of the [Tudat](#) website ([Dirkx et al., 2016](#)) offers two integration tutorials: one involving [RK4](#) and another involving variable step-size Runge-Kutta methods including [RKF45](#). The objective of the tutorial is to get familiar with the different integration methods available in [Tudat](#). At the same time, a small data table has to be reproduced, which also serves as a verification test. For each of the integrators the same problem was addressed: the computation of the velocity of a falling body after a certain amount of time assuming no drag. The results that had to be reproduced are presented in Table 8.1.

Table 8.1: Verification data for the standard integrators

End time [s]	1.0	5.0	15.0	25.0
Velocity [m/s]	-9.81	-49.05	-147.15	-245.25

The first script was written using the instructions from the tutorial and is called `numericalintegrators.cpp`. This script uses the `rungeKutta4Integrator.h` header file and the `RungeKutta4IntegratorXd` function from this header file. This function requires three inputs: the state derivative function (problem specific), an initial time and the initial state. Using the `.integrateTo` extension the end state at a certain end time can be integrated. This requires the end time and the step-size. For [RK4](#) the step-size is constant. This resulted in the same values as presented in Table 8.1.

The second script was used to test the variable step-size integrators (including [RKF45](#)). This script is called `rungekuttavariable.cpp` and uses the `rungeKuttaCoefficients.h` and `rungeKuttaVariableStepSizeIntegrator.h`

header files. In this case the `RungeKuttaVariableStepSizeIntegratorXd` function was used which requires the Runge-Kutta coefficients (from the respective header file), the state derivative function, the initial time, initial state, zero minimum step-size, infinite maximum step-size, relative tolerance and the absolute tolerance as inputs. In this case the integration can be done in individual steps using `.performIntegrationStep` with the current step-size as the only input. The current step-size is computed in the integration method itself, but in this case it is checked to make sure that the step-size does not take the function beyond the specified end time. The integration steps are then repeated until the end time is met. Running this script resulted in the same results as presented in Table 8.1 as well.

These results, combined with the fact that the test files for these two methods produced no errors is proof that they are working accordingly. Thus it can be said that the standard integration methods used in this thesis are verified and ready for use in the optimisation tool. However, during the development of the trajectory propagation tools, the entire tool (including the integrators) will be verified again to determine the performance of the integrators.

79  Explanation of variables:
80  LSTFL = List file name (CON for console listing)
81  OUTFL = Output file name
82  TRAJFL = (Optional) Trajectory input file. File contains time (sec)
83           relative to start time, height (km), latitude (deg),
84           longitude (deg W if LonEW=0, deg E if LonEW=1, see below)
85  profile = (Optional) auxiliary profile input file name
86  WaveFile = (Optional) file for time-dependent wave coefficient data.
87            See file description under parameter iuwave, below.
88  DATADIR = Directory for COSPAR data and topographic height data
89  GCMDIR = Directory for GCM binary data files
90  IERT = 1 for time input as Earth-Receive time (ERT) or 0 Mars-event
91        time (MET)
92  IUTC = 1 for time input as Coordinated Universal Time (UTC), or 0
93        for Terrestrial (Dynamical) Time (TT)
94  MONTH = (Integer) month of year
95  MDAY = (Integer) day of month
96  MYEAR = (Integer) year (4-digit; 1970-2069 can be 2-digit)
97  NPOS = max # positions to evaluate (0 = read data from trajectory
98        input file)
99  IHR = Hour of day (ERT or MET, controlled by IERT and UTC or TT,
100       controlled by IUTC)
101  IMIN = minute of hour (meaning controlled by IERT and IUTC)
102  SEC = seconds of minute (meaning controlled by IERT and IUTC).
103       IHR:IMIN:SEC is time for initial position to be evaluated
104  LonEW = 0 for input and output West longitudes positive; 1 for East
105          longitudes positive
106  Dusttau = Optical depth of background dust level (no time-developing
107            dust storm, just uniformly mixed dust), 0.1 to 3.0, or use
108            0 for assumed seasonal variation of background dust
109  Dustmin = Minimum seasonal dust tau if input Dusttau=0 ( $\geq 0.1$ )
110  Dustmax = Maximum seasonal dust tau if input Dusttau=0 ( $\leq 1.0$ )
111  Dustnu = Parameter for vertical distribution of dust density (Haberle
112          et al., J. Geophys. Res., 104, 8957, 1999)
113  Dustdiam = Dust particle diameter (micrometers, assumed monodisperse)
114  Dustdens = Dust particle density (kg/m3)
115  ALS0 = starting Ls value (degrees) for dust storm (0 = none)
116  ALSDUR = duration (in Ls degrees) for dust storm (default = 48)
117  INTENS = dust storm intensity (0.0 - 3.0)
118  RADMAX = max. radius (km) of dust storm (0 or >10000 = global)
119  DUSTLAT = Latitude (degrees) for center of dust storm
120  DUSTLON = Longitude (degrees) (West positive if LonEW=0, or East

```

```

121         positive if LonEW = 1) for center of dust storm

123           Mars-GRAM 2001 GCM input data sets
124 F107    = 10.7 cm solar flux (10**-22 W/cm**2 at 1 AU)
125 NR1     = starting random number (0 < NR1 < 30000)
126 NVARX   = x-code for plotable output (1=hgt above MOLA areoid).
127           See file xycodes.txt
128 NVARY   = y-code for 3-D plotable output (0 for 2-D plots)
129 LOGSCALE = 0=regular SI units, 1=log-base-10 scale, 2=percentage
130           deviations from COSPAR model, 3=SI units, with density
131           in kg/km**3 (suitable for high altitudes)
132 FLAT    = initial latitude (N positive), degrees
133 FLON    = initial longitude (West positive if LowEW = 0 or East
134           positive if LonEW = 1), degrees
135 FHGT    = initial height (km); ≤-10 means evaluate at surface height;
136           > 3000 km means planeto-centric radius
137 MOLAhgts = 1 for input heights relative to MOLA areoid, otherwise
138           input heights are relative to reference ellipsoid
139 hgtasfcm = height above surface (0-4500 m); use if FHGT ≤ -10. km
140 zoffset  = constant height offset (km) for MTGCM data or constant
141           part of Ls-dependent (Bougher) height offset (0.0 means
142           no constant offset). Positive offset increases density,
143           negative offset decreases density.
144 ibougher = 0 for no Ls-dependent (Bougher) height offset term; 1
145           means add Ls-dependent (Bougher) term, -A*Sin(Ls) (km),
146           to constant term (zoffset) [offset amplitude A = 2.5 for
147           MapYear=0 or 0.5 for MapYear > 0]; 2 means use global mean
148           height offset from data file hgtoffset.dat; 3 means use
149           daily average height offset at local position; 4 means
150           use height offset at current time and local position.
151           Value of zoffset is ignored if ibougher = 2, 3, or 4.
152 DELHGT  = height increment (km) between steps
153 DELLAT  = Latitude increment (deg) between steps (Northward positive)
154 DELLOn  = Longitude increment (deg) between steps (Westward positive
155           if LonEW = 0, Eastward positive if LonEW = 1)
156 DELTIME = time increment (sec) between steps
157 ΔTEX    = adjustment for exospheric temperature (K)
158 profnear = Lat-lon radius (degrees) within which weight for auxiliary
159           profile is 1.0 (Use profnear = 0.0 for no profile input)
160 proffar  = Lat-lon radius (degrees) beyond which weight for auxiliary
161           profile is 0.0
162 rpscale  = random density perturbation scale factor (0-2)
163 rwscale  = random wind perturbation scale factor (≥0)
164 wlscale  = scale factor for perturbation wavelengths (0.1-10)
165 wmscale  = scale factor for mean winds
166 blwinfac = scale factor for boundary layer slope winds (0 = none)
167 NMONTE  = number of Monte Carlo runs
168 iup      = 0 for no LIST and graphics output, or unit number for output
169 WaveA0   = Mean term of longitude-dependent wave multiplier for density
170 WaveDate = Julian date for (primary) peak(s) of wave (0 for no traveling
171           component)
172 WaveA1   = Amplitude of wave-1 component of longitude-dependent wave
173           multiplier for density
174 Wavephi1 = Phase of wave-1 component of longitude-dependent wave
175           multiplier (longitude, with West positive if LonEW = 0,
176           East positive if LonEW = 1)
177 phildot  = Rate of longitude movement (degrees per day) for wave-1
178           component (Westward positive if LonEW = 0, Eastward
179           positive if LonEW = 1)
180 WaveA2   = Amplitude of wave-2 component of longitude-dependent wave
181           multiplier for density
182 Wavephi2 = Phase of wave-2 component of longitude-dependent wave
183           multiplier (longitude, with West positive if LonEW = 0,
184           East positive if LonEW = 1)
185 phi2dot  = Rate of longitude movement (degrees per day) for wave-2
186           component (Westward positive if LonEW = 0, Eastward
187           positive if LonEW = 1)
188 WaveA3   = Amplitude of wave-3 component of longitude-dependent wave
189           multiplier for density
190 Wavephi3 = Phase of wave-3 component of longitude-dependent wave
191           multiplier (longitude, with West positive if LonEW = 0,

```

```

192         East positive if LonEW = 1)
193 phi3dot = Rate of longitude movement (degrees per day) for wave-3
194 component (Westward positive if LonEW = 0, Eastward
195 positive if LonEW = 1)
196 iuwave = Unit number for (Optional) time-dependent wave coefficient
197 data file "WaveFile" (or 0 for none).
198 WaveFile contains time (sec) relative to start time, and
199 wave model coefficients (WaveA0 thru Wavephi3) from the
200 given time to the next time in the data file.
201 Wscale = Vertical scale (km) of longitude-dependent wave damping
202 at altitudes below 100 km ( $10 \leq Wscale \leq 10,000$  km)
203 corlmin = minimum relative step size for perturbation updates
204 (0.0-1.0); 0.0 means always update perturbations, x.x
205 means only update perturbations when corlim > x.x
206 ipclat = 1 for Planeto-centric latitude and height input,
207 0 for Planeto-graphic latitude and height input
208 requa = Equatorial radius (km) for reference ellipsoid
209 rpole = Polar radius (km) for reference ellipsoid
210 idaydata = 1 for daily max/min data output; 0 for none

```

B

ATMOSPHERIC DATA FITTING

In Section 3.4.1 the final results of the atmospheric data fits were presented. However, before those results could be obtained, a few iterations of trial-and-error fits were required. These intermediate trials are presented for both the temperature data, in Appendix B.1, as well as for the density data, in Appendix B.2. The fit requirements for the polynomial function were set such that the errors created by the fit were less than the uncertainty of the latitude and longitude dependent data. This way the desired accuracy could still be reached. This uncertainty is caused by the difference in atmospheric data curves for the different latitudes and longitudes. The atmospheric data curve for the latitude and longitude corresponding to the launch site (21.0 °N and 74.5 °E) was taken as the reference curve and called the launch site curve. The differences between this launch site curve and the 8 other curves were used to define the maximum data curves difference. The *polyfit.m* function within Matlab was used to fit a polynomial to the data. This function also directly provides a standard deviation of the fit for each data point (in combination with the *polyval.m* function). One of the requirements was for the maximum standard deviation of the polynomial fit to be one order less than the maximum difference of the data curves with respect to the launch site curve. The second requirements for a proper fit was for the absolute maximum difference between the polynomial fit and the launch site curve to be less than the absolute maximum difference between the data curves and that same launch site curve.

B.1. TEMPERATURE

Initially, the temperature data curve was split into 6 different sections as portrayed in Figure B.1. The sections were selected on the basis of their individual shapes and the maximum order that was required, where the maximum order for temperature was set at 8. Fewer sections were however always preferred.

Unfortunately, the fourth quarter of section 3 caused this section to not meet the maximum standard deviation requirement because in that quarter the linear behaviour changes directions slightly and the differences between the different data curves become a lot smaller. Therefore section 3 was split into two different sections resulting in a total of 7 sections as shown in Figure B.2.

These sections all met the requirements and thus provided a proper fit to the data. This fit is shown in Figure B.3.

However, because fewer sections were preferred, an attempt was made to reduce the number of sections. Because of the inaccuracy in the Mars-GRAM model close to the planet surface, it was decided to delete the outliers near the surface (section 1) and stretch the outcome of the second polynomial fit to the surface instead. Also, it turned out that section 4 and 5 could be combined in such a way that the requirements were still met. This reduced the number of section from 7 to 5. The final fit was presented in Section 3.4.1 as well as the corresponding errors and polynomial coefficients.

B.2. DENSITY

For the density curve, because the data represents a logarithmic curve, initially an exponential atmosphere was fit. However, this did not meet any of the requirements for a proper fit as can be seen in . This is why a polynomial fit was attempted for the density curve as well with the same requirement as the temperature fits. The first fit was attempted with two sections as presented in Figure B.4.

Figure B.1: Six different temperature curve sections

Figure B.2: Seven different temperature curve sections

However, the second section could not meet the requirements because of the initial part. This is why it was split into two sections as presented in Figure B.5.

This did meet the error requirements and resulted in the fit as shown in Figure B.6 with section 1 being

Figure B.3: All section fits for the launch site temperature data curve

Figure B.4: Two different density curve sections

Figure B.5: Three different density curve sections

the lower part, section 2 the middle and section 3 the upper part.

However, in this case the fit for section three resulted in an oscillating behaviour around the actual data which caused the density values to drop below zero as shown in Figure B.7. Since this is unrealistic, an exponential atmospheric fit for only the third section was attempted (also shown in Figure B.7) however, this resulted in the same behaviour as the attempt for the entire curve. Therefore, it was decided to try a different exponential approach which eventually resulted in the fit described in Section 3.4.1.

Figure B.8 clearly shows that both the full exponential atmospheric fit and the polynomial fits were not a proper choice here. The figure shows the curved part of the curve.

Figure B.6: All section fits for the launch site density data curve

Figure B.8: Zoom in of the end of section 1 with the polynomial and exponential atmospheric fits

C

PROGRAM FILE DEFINITIONS

Both the [RKF](#) and [TSI](#) propagator architectures were presented in Chapter 7 (Figures 7.3 and 7.4 respectively). These included many different operation blocks. Each block is either a separate class, a combination of a header and source file (without it being a class), a function of either of these files or a function in the main file (MAVPropagator). The different files that include several blocks are MAVPropagator.h/.cpp, TaylorSeriesIntegration.h/.cpp, ascentDragForce.h/.cpp and ascentStateDerivativeFunction.h/.cpp, where this last file is also a class. The functions that will be implemented in these files are mentioned in Table C.1 all other blocks are described in Table C.2.

Table C.1: Large program files and included functions.

MAVPropagator	TaylorSeriesIntegration	ascentStateDerivativeFunction
Update current state	Compute auxiliaries	Compute current spherical state
Integration step	Thrust acceleration in B-frame	Compute gravitational acceleration
	Compute Taylor coefficients	Compute thrust and drag acceleration
ascentDragForce	Store state Taylor coefficients	Transfer to inertial frame
Compute speed of sound and Mach number	Initial step-size	Compute total acceleration
	Provide Taylor series expansion	Compute mass flow rate
	Estimate the max. trunc. error	
Compute drag force	Taylor series expansion incl. trunc. error	

Table C.2: Separate function files

Block	Kind of file
Planet characteristics	Class
Vehicle characteristics	Class
Auxiliary equations, derivatives and functions	Class
Current state and time	Class
Basic recurrence relations	Header and source
Full set of recurrence relations	Header and source
Determine next step-size	Header and source
Compute local air temperature	Header and source
Compute local air density	Header and source
Compute drag coefficient	Header and source

D

ALL RECURRENCE RELATIONS

In this appendix, all the reduced auxiliary functions that form the complete recurrence relations for each of the variables using the basic recurrence relations are provided for all three cases. Each case contains a table with the function definition, the corresponding equation and the basic recurrence relation category. All the reduced auxiliary derivatives are also described. All these expressions are a function of k , where $W(k)$ refers to the k^{th} order reduced derivative. The same holds for $X(k)$ and $U(k)$. All the expressions hold for $k \geq 1$. In the tables, the (k) is neglected to make it more readable.

D.1. FIRST CARTESIAN CASE: EULER ANGLES

The first Cartesian case requires a large number of reduced auxiliary functions. These are all provided in Table D.1. For each function, the number, the equations and the category is provided.

Table D.1: Reduced auxiliary functions for the first Cartesian case.

Auxiliary function	Equation	Category
$W_{4,1} =$	$X_1^2 + X_2^2$	Multiplication
$W_{4,2} =$	$W_{4,1} + X_3^2$	Multiplication
$W_{4,3} =$	$\sqrt{W_{4,2}}$	Power
$W_{4,4} =$	$\sqrt{W_{4,1}}$	Power

The complete recurrence relation for each of the auxiliary variables can now be written as a function of the reduced auxiliary functions. These are shown by Equation (D.1) and hold for $k \geq 1$.

$$\begin{aligned}
 U_1(k) &= X_4(k) = \frac{U_4(k-1)}{k} & U_5(k) &= W_{5,6}(k) \\
 U_2(k) &= X_5(k) = \frac{U_5(k-1)}{k} & U_6(k) &= W_{6,7}(k) \\
 U_3(k) &= X_6(k) = \frac{U_6(k-1)}{k} & U_7(k) &= 0 \\
 U_4(k) &= W_{4,52}(k) & U_8(k) &= 2W_{8,1}(k) + 2W_{8,2}(k) + 2W_{8,3}(k) \\
 & & U_9(k) &= \frac{3}{2} W_{9,1}(k)
 \end{aligned} \tag{D.1}$$

These equations are now all a function of the recurrence relations corresponding to the rest of the auxiliary functions, which are all basic recurrence relations as mentioned in Table D.1.

D.2. SECOND CARTESIAN CASE: UNIT VECTORS

The second Cartesian case is similar to the first one, however fewer reduced auxiliary functions are needed. These are all provided in Table D.2. For each function, the number, the equations and the category is provided. The numbers are not always the same as in the first case, so these should be read as completely new reduced auxiliary functions. In this case, u_4 , u_5 and u_6 are included in the table, because they were defined as recurrence multiplication relations.

Table D.2: Reduced auxiliary functions for the second Cartesian case.

---------------	-------------------------------------	----------------

The complete recurrence relation for each of the auxiliary variables can again be written as a function of the reduced auxiliary functions. These are shown by Equation (D.2).

$$\begin{aligned}
U_1(k) &= X_4(k) = \frac{U_4(k-1)}{k} \\
U_2(k) &= X_5(k) = \frac{U_5(k-1)}{k} \\
U_3(k) &= X_6(k) = \frac{U_6(k-1)}{k} \\
U_4(k) &= W_{4,39}(k) + W_{4,36}(k) W_{4,13}(k) + W_{4,37}(k) W_{4,21}(k) - W_{4,38}(k) W_{4,24}(k) \\
U_5(k) &= W_{5,1}(k) + W_{4,36}(k) W_{4,14}(k) + W_{4,37}(k) W_{4,22}(k) - W_{4,38}(k) W_{4,25}(k) \\
U_6(k) &= W_{6,1}(k) + W_{4,36}(k) W_{4,15}(k) + W_{4,37}(k) W_{4,23}(k) - W_{4,38}(k) W_{4,40}(k) \\
U_7(k) &= 0 \\
U_8(k) &= 2W_{8,1}(k) + 2W_{8,2}(k) + 2W_{8,3}(k) \\
U_9(k) &= \frac{3}{2} W_{9,1}(k)
\end{aligned} \tag{D.2}$$

D.3. SPHERICAL CASE

Since the Spherical case is very different from the Cartesian cases, it comes with its own auxiliary functions. The reduced versions are shown in Table D.3.

Table D.3: Reduced auxiliary functions for the Spherical case.

Auxiliary function	Equation	Category

$W_{27,6} =$	$X_{15} (W_{27,4} + W_{27,5})$	Multiplication
$W_{28,1} =$	$U_{30} X_{28}$	Multiplication
$W_{29,1} =$	$\begin{cases} 0, & \text{for } 0 \leq M < 0.5 \\ P_{CD1,2} U_{32}, & \text{for } 0.5 \leq M < 1 \\ P_{CD1,3} U_{32}, & \text{for } 1 \leq M < 1.3 \\ P_{CD1,4} U_{32}, & \text{for } 1.3 \leq M < 2.5 \\ P_{CD1,5} U_{32}, & \text{for } 2.5 \leq M < 4 \\ 0, & \text{for } M \geq 4 \end{cases}$	Constant Multiplication
$W_{30,1} =$	X_{31}^9	Power
$W_{30,2} =$	X_{31}^8	Power
$W_{30,3} =$	X_{31}^7	Power
$W_{30,4} =$	X_{31}^6	Power
$W_{30,5} =$	X_{31}^5	Power
$W_{30,6} =$	X_{31}^4	Power
$W_{30,7} =$	X_{31}^3	Power
$W_{30,8} =$	X_{31}^2	Multiplication
$W_{30,9} =$	$U_{31} (10P_{\rho 10} W_{30,1} + \dots + 3P_{\rho 3} W_{30,8} + 2P_{\rho 2} X_{31} + P_{\rho 1})$	Multiplication
$W_{32,1} =$	$X_{33} U_{15}$	Multiplication
$W_{32,2} =$	$X_{15} U_{33}$	Multiplication
$W_{32,3} =$	X_{33}^2	Multiplication
$W_{32,4} =$	$\frac{W_{32,1} - W_{32,2}}{W_{32,3}}$	Division

$W_{33,1} =$	$\frac{U_{34}}{X_{33}}$	Division
$W_{34,1} =$	$\begin{cases} P_{T1,1} U_{31}, & \text{for } -0.6 \leq h < 5.04 \\ (3P_{T3,2} W_{30,8} + 2P_{T2,2} X_{31}) U_{31} + P_{T1,2} U_{31}, & \text{for } 5.04 \leq h < 35.53 \\ (6P_{T6,3} W_{30,5} + 5P_{T5,3} W_{30,6} + 4P_{T4,3} W_{30,7} + \dots \\ \dots + 3P_{T3,3} W_{30,8} + 2P_{T2,3} X_{31}) U_{31} + P_{T1,3} U_{31}, & \text{for } 35.53 \leq h < 75.07 \\ (8P_{T8,4} W_{30,3} + 7P_{T7,4} W_{30,4} + 6P_{T6,4} W_{30,5} + 5P_{T5,4} W_{30,6} + \dots \\ \dots + 4P_{T4,4} W_{30,7} + 3P_{T3,4} W_{30,8} + 2P_{T2,4} X_{31}) U_{31} + P_{T1,4} U_{31}, & \text{for } 75.07 \leq h < 170.05 \\ 0, & \text{for } h \geq 170.05 \end{cases}$	Multiplication

In this case, a number of extra auxiliary equations were used, which result in extra recurrence relations. These are all described in Equation (D.3) and hold for $k \geq 1$.

$$\begin{aligned}
 U_7(k) &= 0 & U_{27}(k) &= \frac{1}{2} S W_{27,6}(k) \\
 U_{11}(k) &= W_{11,3}(k) & U_{28}(k) &= W_{28,1}(k) \\
 U_{12}(k) &= W_{12,1}(k) & U_{29}(k) &= W_{29,1}(k) \\
 U_{13}(k) &= W_{13,9}(k) & U_{30}(k) &= W_{30,9}(k) \\
 U_{14}(k) &= W_{14,7}(k) & U_{31}(k) &= U_{16}(k) \\
 U_{15}(k) &= W_{15,6}(k) & U_{32}(k) &= W_{32,4}(k) \\
 U_{16}(k) &= W_{16,1}(k) & U_{33}(k) &= W_{33,1}(k) \\
 & & U_{34}(k) &= W_{34,1}(k)
 \end{aligned} \tag{D.3}$$
